Another variant of a constructivist perspective are political rhetoric approaches that take up a critical stance toward conventional models of decision making and psychological functioning, arguing that dispute and conflict are essential features of political thought and behavior (Condor et al., 2013). According to this line of work, citizens are embedded in a sociocultural environment characterized by ideological dilemmas and opposing worldviews that shape citizens' attitudes toward political issues. Rather than being expressions of an irrational common sense, such contradictions are the preconditions for political thought and for rhetorical deliberation within and between members of a society, and consequently for a lively democratic political culture.

Group-Level Processes

International Conflict

Research on international relations and international conflict is a traditionally important aspect of political psychology. Rooted in a social psychological perspective, this strand of research offers a complementary view on structural, strategic, and realist analyses of international conflict. It assumes that subjective perceptions of the conflict determine actions and responses by the conflicting parties, that these perceptions develop in the context of dynamic and changing intergroup relations, and that ongoing interaction between conflicting parties determines the development and outcome of the conflict (Fisher et al., 2013). International conflict is thus a process driven by collective needs and fears rather than by objective national interests, in particular concerning identity, recognition, and autonomy of ethnonational groups.

This focus on subjective perceptions of conflict is evident in research on stereotypical images of countries. These images are held by both the general population and political elites and define the perceived threats and opportunities countries are confronted with. They are stable, difficult to change, and easily become taken-for-granted assumptions that produce routinized responses of what is seen as in a country's interest or against it. A limited number of such images seem to organize international relations, including enemy, ally, degenerate, colony, and barbarian images (Herrmann, 2013). An enemy image implies, for example, a tendency to dehumanize its population and to interpret any activity by its government as evidence of resolve and aggressive intent. Hence, international relations are severely prone to misperceptions with potentially catastrophic consequences; for example, when a military conflict escalates due to distorted or selective perceptions of the conflict situation. Other factors that have been shown to contribute to conflict escalation are the normative reinforcement of bellicose attitudes in times of conflict and psychological commitments that prevent individuals and groups deeply involved in the conflict to actively engage in deescalation and conflict resolution. This is the case when worldviews are so strongly built around the conflict that they would be threatened by an end to the conflict.

Racism and Politics

Negative attitudes toward groups – prejudice – is another central group-level topic addressed by political psychologists. This research has its roots in U.S. American race relations that have shaped American political debate since the nineteenth century. The current state of research on the role of prejudice in politics can be traced back to the 1960s, a period during which a number of crucial changes in American race relations have occurred, most notably the Civil Rights Act of 1964 that outlawed any institutionalized discrimination based on racial criteria. Up to this period, overt and blatant racism against Blacks was largely seen as legitimate, but with the deep changes of the racial relations following the civil rights era, beliefs about biological inferiority of Blacks became more and more unacceptable. Instead, new, more subtle forms of racism emerged, called symbolic, modern, or ambivalent racism that were characterized by the rejection of claims about biological inferiority and instead emphasized value differences between racial groups and value violations by Blacks (e.g., in claims that racial inequality was due to lacking work ethic by Blacks).

It is in this context that researchers have studied the role of prejudice and racism in American politics (see Kinder, 2013). Research has shown that racial animosity played and still plays a central role in many political processes, including party identification, voting, and policy opinions. Identification with the Republican and the Democratic Party closely follows racial divides, following the major political realignment in 1964 that shifted Blacks' identification from the Republican to the Democratic Party in the wake of the parties' starkly opposing positions on the Civil Rights Act.

Racial prejudice may act as a shortcut to political decisions regarding support or opposition to social policies. Many studies have demonstrated that public opinion is shaped by the attitudes citizens hold toward the groups deemed to be beneficiaries or victims of a given policy, in particular concerning measures destined to correct social inequalities (e.g., welfare, employment, and affirmative action policies). Prejudice has been shown to explain widespread opposition to welfare (Gilens, 1999), and the fierce opposition to the Affordable Care Act (Obamacare) in 2013 can also be seen as being based on racial resentment. It must be noted, though, that the interpretation of the observed relationships between prejudice and political outcomes is itself hotly debated. For some, the effects are a mere expression of principled conservatism without any connection to prejudice, whereas for others cumulated survey evidence is proof enough that prejudice plays the assumed causal role in these political processes.

Group Identities and Cultural Diversity

The recent focus on issues of social change and political legitimacy has led to an intensified use of theories of intergroup relations and political identities in political psychology. These

approaches conceptualize groups as the link between societal conditions and psychological processes to address issues such as multiculturalism, social inequality, intergroup dominance, and discrimination from the perspective of political psychology. In line with the principle that political thought and behavior is context dependent, many approaches further assume that psychological processes are contingent upon the social position of individuals. Research therefore challenges the idea of universal psychological processes and differentiates analyses of psychological processes between dominant versus subordinate groups, or between ethnic majority versus minority groups.

A key concept in this intergroup approach to political psychology is political identity. Based on different intergroup approaches developed in social psychology (e.g., Social Identity Theory, Realistic Conflict Theory), political identities refer to identification with and meaning attributed to membership in politically relevant groups, including political parties and national, ethnic, linguistic, or gender groups (Huddy, 2013). Research has, for example, shown that individuals who strongly identify with their group are more likely to act on behalf of a group-related cause, to view the political environment in antagonistic terms, and to act defensively in face of group criticism.

Cultural diversity of contemporary societies provides the background to much of group identity and intergroup relations research in political psychology (Green and Staerklé, 2013). The most widely studied instances of (majority) group identity concern different forms of national attachment and identification. Two broad forms can be distinguished: patriotism denotes positive feelings of pride toward the nation and its symbols. It may be accompanied by critical attitudes that invite group members to speak up and criticize the nation when necessary. While patriotism is fundamentally non-comparative, nationalism, in turn, together with its derived forms of chauvinism and blind patriotism, is a comparative form of attachment that asserts national superiority in comparison to other countries, and may in its extreme form question the mere presence of immigrant and other minority groups on national soil.

A related strand of research is concerned with the ways majority members of receiving societies react to the presence of migrant groups, often based on analyses of perceived symbolic and material threat evoked by immigrants and of various forms of intergroup contact. New developments include the widespread use of multilevel techniques to examine the role of political and ideological contexts (assessed with macro-level measures at the national or regional level, e.g., strength of political parties) in explanations of hostile attitudes and behaviors toward immigrants.

Even though group identities are important for both majority and minority groups, their role in political processes has often been studied with minority groups, in particular ethnic or migrant groups. Strong minority group identities increase, for example, the likelihood that group members define their (material) interests according to the collective interests of the group rather than as a function of their individual self-interest. Highly identified minority group members develop a sense of common fate with other group members that leads them to express claims and grievances in the name of the group and to defend their own and fellow group members' interests.

Other research has examined subjective migrant experiences within receiving societies from a discursive perspective, focusing on the active construction of intercultural identities and everyday practices of intercultural interactions. Studies have, for example, shown that while ethnic identities involve beliefs in commonality, shared kinship, and ancestry, they also capture processes of ongoing negotiation of ethnic boundaries, both within the migrant group (e.g., regarding the maintenance of cultural traditions in the receiving society) and between the migrant group and the receiving society (e.g., the nature of assimilation).

Social Change and Collective Action

Research on civic participation and collective action in political and social psychology has increased significantly as part of the new interest of researchers in issues of social change and contestation. This increase goes hand in hand with the rise of social movements all around the world during the past two decades. Collective action research is concerned with movement politics as opposed to party politics, that is, with active participation in mass demonstrations, protest events, occupations of public sites, boycotts, blockades, riots, and the like (Klandermans and van Stekelenburg, 2013).

Early approaches to collective action in the 1950s and 1960s explained protest by high levels of discontent experienced by individuals, followed by resource mobilization and political process theories that claimed that aggrieved people engage in collective action when the necessary organizational resources are available. Within these structural approaches, participation in collective movements was explained with rational choice models according to which individuals evaluate the costs and benefits of participation.

In the early 1990s, new social constructionist approaches to protest began to emerge in response to the dominant structural approach. These new approaches attempted to move away from static, decontextualized explanations of protest to more dynamic and contextualized models. These new models highlighted processes of social interaction and negotiation among participants, opponents, and bystanders, and analyzed the role of collective emotions and subjective definitions of the situation to explain collective action. In line with earlier theories, grievances, opportunities, and resources were still required, but grievances were understood as more nuanced responses to illegitimate inequality (assessed with judgments of distributive justice and group relative deprivation), suddenly imposed grievances (e.g., new roads or buildings) and violated principles (e.g., betrayed trust).

Moreover, since grievances are ubiquitous in contemporary society, the more important question now was to examine the circumstances under which grievances do actually give rise to actual protest movements. To answer this question, the various contemporary theoretical frameworks on collective action converge on the key role played by two factors: first, a politicized collective identity is a crucial component of engagement in collective political action. Many studies have shown that the more individuals identify with a group involved in a protest activity, the more likely they are to participate in that activity.

Movements offer indeed the opportunity to act on behalf of one's group and to celebrate the collective identity with symbols, rituals, marches, and songs. The second factor is efficacy as the belief that the movement will be able to redress grievances effectively. In addition, ideological motivations and intergroup emotions (in particular anger) have also been identified as key antecedents of collective actions.

Once these elements are in place, organizational processes involved in the mobilization of protesters explain collective action. Mobilization processes turn sympathizers into active participants and transform grievances into political claims. Through them, movements attempt to disseminate their analysis of the situation, create moral outrage among participants, and point out targets. Discursive approaches highlight identity functions of mobilization discourse: political communicators may attempt to regroup a heterogeneous audience into a single rhetorical entity ('we are the 99%') or to present a political program as an instantiation of the dominant norms and values of a given identity category ('we all welcome foreigners in our community'). Finally, researchers now recognize the importance of virtual networks and social media such as Twitter and Facebook in shaping 'connective action,' but the actual workings of these new forms of mobilization leading to coordinated collective action are currently far from clear.

Political Religions: History of the Concept

Sabine A Haring, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The history of Western modernity must not only be regarded as a linear process of secularization. It is rather characterized by the ambiguities of the modern age, by both the 'disenchantment' and the 'reenchantment.' Worldly replacements such as science and political movements partly took over the function and the meaning of traditional religions. Political 'religions' not only adopted, transformed and amalgamated the contents of Christian texts and imaginations and used Christian rites and symbols, but also fulfilled special functions for their 'believers.' This article discusses the history of the concept 'political religion' from the period when Voegelin's book 'The Political Religions' was published in 1938 to recent works concerning the topic.

Introduction

The development of modern western societies is the result of a number of transformation processes in the fields of politics, economy, law, and culture which can be described in more detail by terms such as democratization, industrialization, urbanization, secularization, rationalization, and individualization. In the social-scientific discourse since the 1950s these processes have mostly been subsumed under the term 'modernization' (Haring and Scherke, 2000). Analogously to the predominant insight in the current debate that there is no empirical evidence for any universal modernization process concerning the different societal subsystems and therefore we have to speak of several kinds of modernity or different ways of modernization, also a concept of secularization which equates 'secularization' with increasing rationalization seems to have become obsolete. More recent research shows on the one hand that the idea of secularization being an integral element of modernization *cannot* be transferred to non-Western societies but that rather the West is the exception from the global rule. On the other hand this indicates that also the history of western modernity cannot be described as a simple, linear-progressive process of secularization but shows a variety of sometimes even contradicting tendencies of secularization and resacralization (Hildebrandt et al., 2001). Modernity cannot be described only as a period of pluralism, subjectivism and the destruction of all intellectual and moral foundations; the radical questioning of all traditional values produced also a search for unity behind particular phenomena, a search for new foundations, systems and structures. In this context, as Haring demonstrates (2008), 'reenchantment' appeared in the specific guise of traditional religions as well as worldly substitutes for religion took over the *topics* and *functions* of traditional religions. Although Norbert Elias observed in certain fields the intrusion and finally predominance of scientific explanations, in "social matters, people are exposed even today to pressures and anxieties they cannot comprehend. Since people in distress are unable to live without some explanation, the gaps in understanding are filled out by fantasy." (Elias, 1978, p. 27) (As one example of providing explanations for social distress and excitement, Elias gives the 'National Socialist myth.') Precisely in times of growing insecurity and lack of orientation – for example after the traumatic experiences during and after the First World War – many people tend toward gathering even more closely around the ancient gods, toward erecting new idols, or toward leaving themselves to the uncoordinated, chaotic course of events (see Gadshijew, 1996, p. 76).

In the interwar period the contemporaries tried to interpret and understand the development of these new totalitarian regimes. Thus, the ways in which the new revolutionary regimes referred to themselves – Communism, Fascism, National Socialism – were joined by references by others; at first travelers, journalists, and writers told about those political movements which had newly come to power. Soon one tried to find appropriate names for these new phenomena; they became the topic of an international philosophical-political debate. Finally these attempts at new concepts and terms for the new political movements resulted in larger patterns of interpretation: the concepts of totalitarianism and of political religions are considered the best-known ones (see Maier, 2003, p. 9). One tried to grasp common grounds of National Socialism and Stalinism by help of the totalitarianism concept. Authors such as Eric Voegelin, on the other hand, by employing the concept of political or secular religions, focused on the religious dimension of the totalitarian movements. As Hans Maier (p. 19) points out, the 'classical' vocabulary was most present (and was systematically renewed also at a later stage) in the Anglo-Saxon countries, whereas it looks most marginalized in Germany and Italy. In these countries the concept of dictatorship has been reactivated during the 1920s. In remaining Europe, after 1923 and after 1938 the concepts of totalitarianism and political religions have been spreading. In this context, 'mediators' of East European origin, such as Waldemar Gurian (and later Zbigniew Brzezinski), exert crucial influence. Then in the 1930 and 1940s the totalitarianism thesis conquers also the Anglo-Saxon countries. However, there it is always challenged to a certain degree. Even an important supporter of the totalitarianism concept such as George Orwell, whose attention is most of all attracted by what happens in Germany and Russia, uses the adjective 'totalitarian' as a synonym of 'tyrannical' and 'despotic.' Against the background of the new political movements and regimes the concept of 'political religion' tries to emphasize the specific changing relationships between religion and politics and especially between religion and totalitarianism. (On the different analyses of the complex

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03110-X

relationships between religion and politics see Lovin, 1992; Gebhardt, 1995.) Emilio Gentile shows that "practically every scholar of totalitarianism during the interwar period […] agree that the sacralisation of politics (variously defined as lay religion, secular religion, earthly religion, political religion, political mysticism, and political idolatry) was one of the most distinctive elements, if not the most dangerous, of the totalitarian phenomenon" (Gentile, 2000, p. 18).

Eric Voegelin

In most cases, the various contributions to the topic of 'political religions' start out from political scientist and philosopher Eric Voegelin, whose work has attracted more attention in the German-speaking countries only in the past 10 years. Voegelin – just as French sociologist Raymond Aron, with whom he corresponded for years (Weiss, 2003, pp. 41–42) – interpreted the ideological movements of the twentieth century as *one* kind of 'religion' in so far as they enriched their essential symbols with sacral substance, to *affectively* bind the masses and make them expect salvation in a way which could be politically exploited.

Voegelin's book *The Political Religions* – published by Bermann-Fischer in Vienna in the month of Austria's annexation to the Reich and just a few months before his flight to the USA – marks a break in his works. (In his early period of work, he had first of all been dealing with issues of political science, constitutional theory, legal theory and empirical cultural sciences. However, with the publication of *The Political Religions* these issues increasingly retreated to the back, and from then on Voegelin dealt predominantly with his political theology and philosophy of history. See Henkel, 1998, p. 10–11, 25 as well as 169; Porter, 2002, most of all 151–160.) As Voegelin remarked in his *Autobiographical Reflections*, the choice of this title was based on certain contemporary analyses – as examples he gave Louis Rougier's study 'Les mystiques politiques' (contemporaines et leurs incidences internationals from the year 1935; the author) – which emphasized the religious dimension of ideological movements (Voegelin, 1994, p. 70). Now, in *The Political Religion* Voegelin assumed that main experiences his/her existence as "being natural (kreatürlich) and, therefore, questionable" (Voegelin, 2000, p. 30). The wealth of the different ways and degrees in which humans perceive this and finally indeed express it "unfolds on one single dimension of religious experience, namely, in connection with the agitations of naturalness" (p. 31). In this context, whole worlds of symbols, linguistic signs and concepts organize themselves around the respective holy center. Finally they consolidate to systems that can be grasped with the help of the spirit of religious excitement and can be fanatically defended as the 'correct' order of being.

By referring explicitly to Scheler, particularly to the latter's work *Die Stellung des Menschen im Kosmos*, Voegelin started out from certain basic anthropological assumptions: both the realm of politics and the realm of religion are said to have common roots in human nature which is a unity and must be accepted as a unity. (Voegelin dissolved the antagonistic relation between religion and politics, which had developed in the course of the Modern Age.) In *Race and State* (1933), he had discussed the problem of the connection between bodily physical and spiritual-political existence (Voegelin, 1994, pp. 34–37), in *The Political Religion*, he turned to the connection between religious and political existence by trying to work out the religious nature of political mass movements – having in mind first of all National Socialism and Italian Fascism. (H.C. Kraus considers precisely the new way of defining the relation of politics and religion that what makes Voegelin's approach fruitful; and that precisely at a time "when awareness of this had almost been lost." See Kraus, 1997, p. 80.) Voegelin considered precisely the present as he experienced it to be characterized by a multitude of 'religious' orders being at work. Man, he stated, is torn apart, the old certainities have dissolved: "And wide is the space for places of the soul from which ecstasies arise, the experiences in which humans transcend their existence: from the *unio mystica* in spirit to the exaltation in the celebration of community, to the dedication to the fraternity of companions, to the loving extension of oneself into the landscape, the plants and the animals, up to carnal convulsion in the sexual act and in bloodlust." (Voegelin, 2000, p. 33)

His writings were influenced, among others, by his teachers Othmar Spann and Hans Kelsen (Voegelin, 1994, pp. 19–25, 38–41; Neisser, 2003, pp. 19–25), by Max and Alfred Weber, but also by the Stefan circle around Stefan George as well as by Karl Kraus (Porter, 2002, pp. 154–155), by Max Scheler, John Dewey and William James (Voegelin, 1994, pp. 46–48, 92–93), the philosophers and theologians of Neo Thomism – G. Sertillanges, J. Maritain and E. Gilson – as well as by Henri Bergson and the members of the so called 'Geistkreis' (Voegelin, 1994, pp. 23–25; Herz, 1996, pp. 195–204) named several elements of the symbolic forms that ca be found in all "very advanced civilizations": "the hierarchy, in which the sacral substance branches out from a transcendent God to the community of creatures; the ecclesia as the sacral communal substance; the apocalypse as the revelation of the empire; the holy kings as God's mediators and personality carries of the community" (Voegelin, 2000, pp. 70–71).

Hierarchy and Ecclesia

The clearly determined sacral hierarchy reached from the divine top via the hierarchy of rulers and offices as far as to the last obedient subject. It was symbolically expressed, for example, by the image of the sacral outpouring: Pharaoh Akhenaton's sun cult, which is said to have much influenced Plotin, the symbol of outpouring in Maimonides, the rays of light in Dante's 'Monarchia, ' and Louis XIV's sun image illustrate the continuity of symbolic manifestations over long time periods. Finally Bodin, the great theoretician of the French monarchy, is said to have rationalized the symbol of the sacral hierarchy as far as to the finest details of state and legal hierarchy. Another kind of symbol which has been transformed from being sacral to being secular is the 'ecclesia.' The process of closing off a hierarchically organized community, Voegelin (pp. 44–50) stated, had demanded that unity experienced itself as a center of existence resting within itself. However, finally the concept of Christianity – as it was developed in the epistles of Paul and the closely related Epistle to the Hebrews – understood the 'ecclesia,' the community, to be the mystical Body of the Christ

(p. 45). The offices of the 'ecclesia' were organized like the 'limbs' of the body, to then, finally, form the unity of the earthly body, with Christ being its *pneuma*. The model of the early community, as it had been drafted by Paul, could be extended by political functions of the ruler, which way the ruler's function was given its status within the *corpus mysticum*. Throughout all transformations of the Christian 'concept of the ecclesia,' Voegelin pointed out (pp. 45–47), a basic frame was kept, which became obvious both in terms of Christian Churches and the state communities. But not only there: The concept of freedom and equality served as the state religion during the French Revolution, the Pauline concept of extending the *corpus mysticum* toward mutually completing functions of the community was introduced into the theories on the division of labor of British and French economists and sociologists, and the demand for spiritual conformity as the basic form of the mystic corpus which was united by the *pneuma* was still alive in, for example, the political religion of National Socialism.

Another process which was significant for the development of inner-worldly communities, Voegelin said (pp. 47–50), was the split of the 'ecclesia' into the 'spiritual' and 'temporal' lines: as examples of this Voegelin gave St. Augustine's distinction of the heavenly and the earthly civitas as well as St. Thomas Aquinas's definition of the relation of the functions of Church and Prince. Finally, the contradictions between 'spiritual' and 'temporal' had become meaningless, after the occidental 'ecclesia' had dissolved into state subcommunities. The 'ecclesia' became one particular community out of others; state and Church formed a close unity which made any distinction obsolete, although not all parts of Europe experienced this development at the same time. "In the course of the political-religious history of Europe," as Voegelin emphasized, "the particular ecclesia developed further into a closed, inner-worldly ecclesia and also gave rise to the corresponding empires of Satan." (p. 58) After all, the symbolism of the completely secluded inner-worldly 'ecclesia' needed only one short step beyond the symbol of the Leviathan, although now the connection to God had been cut and replaced – in its function as a legitimation of the community as a person – by the community itself. (For Voegelin the great theologian of the particular 'ecclesia' was Thomas Hobbes, the creator of Leviathan. See Voegelin, 2000, pp. 53–58.)

For the explanations on hierarchy and 'ecclesia,' history was observed so to speak from the outside, as a sequence of changes of a world of religious symbols. By a next step, in his explanations on the apocalypse, Voegelin discussed the "interpretation of the development from inside, from the standpoint of the people and powers involved" (p. 50).

Apocalypse

The basic structure of a religious interpretation of history had already been found in the Pauline classification of world history into three areas (p. 50): the *lex naturalis*, the *lex mosaica* of the Old Testament, and third the Christian empire; however it was further developed by being enriched with topics which were of significance for each respective period. In this context the topic was understood to be an expression of God's will in history, the Holy Numbers functioning as a rational structure: the 'three' of the Trinity, the 'seven' for the gifts of the Holy Spirit, the hexameron, the 6 days of creation, the Old Testament's 42 generations from Abraham to Christ, and half of that number as represented by the 21 generations before Abraham. According to Voegelin (pp. 51–52), it was Joachim of Fiore (around 1132-1202) who, by his Trinitarian eschatology, defined the symbols which, up to our days, determine the self-interpretation of the modern political community: firstly, understanding history as a sequence of three ages, the last of which will be the Third Empire – an idea which is found both in the humanist and encyclopedic structuring of history into antiquity, the Middle Ages and the Modern Age and in the models of Turgot and Comte, of Hegel and Marx as well as in the National Socialist symbol of the Third Reich; secondly, the symbol of the leader, which is found, for example, with the sect movements during the Renaissance and the Reformation as well as in Dante or Condorcet, in Comte and Marx; thirdly, the symbol of the prophet of the new age which implicitly assumes that history as a whole is open to human recognition – may it be by way of revelation or speculative gnosis; and fourthly, the symbol of the brotherhood of autonomous individuals, meaning the abandoning of institutions, still had the abandoning of the Church in mind, which as a mediator for grace and administer of the sacraments will finally become obsolete because in the third age the humans will have direct access to salvation. This idea of a community of perfected humanity without any institutional authority was soon found – in various ways – with the sects of the Middle Ages and the Renaissance as well as with the Puritan Churches of the Saints (see Voegelin, 1999, pp. 113–116). Finally, the immanentization of the meaning of history, which was started already by Joachim, was fully developed by the process of secularization with thinkers such as Comte and Marx, where finally the meaning of history became a completely inner-worldly phenomenon without any transcendental breaks. In the nineteenth century, Voegelin says, 'metaphysics' became a bad term and religion was discredited as the 'opium of the people' or unmasked as an 'illusion.' However 'counter-formulas' to the 'spiritual religions': the 'scientific Weltanschauungen,' 'scientific Socialism,' the 'scientific race theory' (p. 60) developed. But as the humans are not able to make the problems of their existence disappear, even if God has become invisible behind the modern concept of the world, the topics of the world have become new gods. According to Voegelin (pp. 60–62) both, Christian and inner-worldly religions, have their own apocalypse, although the latter takes the symbols it creates from the stock of the sciences. Here, the Final Empire is no longer a heavenly community of the spirit but an earthly state of perfected mankind. Kant, Fichte, Comte and Marx developed models which were appropriate to this postulate and also created the appropriate symbolism of the devil.

Belief (Glaube)

Finally, at the end of *The Political Religions*, Voegelin returned to his initial consideration: from the experience of being a creature there develops the longing to go beyond the conditions of human existence and to be dissolved and redeemed by something which is beyond man, greater than man and more perfected than man. Analyzing Gerhard Schumann's *Lieder vom Reich*, one of the "strongest expressions of political-religious

agitation" (p. 67), he sketched those movements of the soul "that form the basis for the symbols and historical reality of the inner-wordly community" (p. 67). As forms of religious excitement, they are rooted "in the experience of creatureliness, but the *realissimum* in which they find redemption are not spiritual but enchored in desire, and they end in the bloodlust of the deed" (p. 67) (By Schumann, Voegelin selected a National Socialist *par excellence* who is considered an exemplary representative of the young generation of National Socialists, in particular of a group of authors born between 1905 and 1914, among whom there counted a. o. Hans Baumann, Herbert Böhme, Kurt Eggers, Herybert Menzel, Eberhard Wolfgang Möller, Hans Jürgen Nierentz and Baldur von Schirach. See Vondung, 1997, p. 22.).

Voegelin interpreted National Socialism as a religion less because it had adopted symbols of the Christian language and cultic practices of the Christian Church but rather due to the fact that National Socialism was based on religious experiences which, he said, had led to the manifestation of a new *realissimum*. That subcontent of the world which the National Socialists had made their *realissimum* was the ethnic community (*Volksgemeinschaft*) as a unity of common blood, which Voegelin called a particular 'ecclesia' in contrast to the universal Christian 'ecclesia.' Already in the late 1930s his analyses made aware of the *ambivalences* of the Modern Age. Voegelin did not revise the thesis according to which the rise of the ideological mass movements was based on essential religious needs of broad parts of the population, which were met by these ideologies, even if later, in his book *Science, Politics and Gnosticism* he called the term 'political religions' a 'makeshift solution' (Voegelin, 1994, p. 70) which now had to be replaced by 'Gnosticism.' (During his *Walgreen Lectures* at the University of Chicago, as Henkel points out (1998, pp. 49, 75), Voegelin had for the first time developed the Gnosticism thesis by its more extended theoretical and historical embedding. He used the category of Gnosticism, by which originally one meant religious sects on the Mediterranean in late antiquity, a. o. to characterize ideologies and – following Max Weber – based his interpretation of history on it, in the sense of a 'pneuma-pathological idealtype' (G. Weiss) which found expression by many realizations.) After all, he interpreted the political mass movements such as National Socialism and Italian Fascism as expressions and symptoms of a severe crisis of western civilization, as heresies which do not do justice to the essence of man.

From Rudolf Otto to Waldemar Gurian

That modern political movements can be described and categorized with the help of religious categories can only be explained against the background of religious-philosophical and phenomenological research which started already before the First World War. Here the concept of religion – if we just consider Otto (*Das Heilige – Über das Irrationale in der Idee des Göttlichen und sein Verhältnis zum Rationalen*, published at Breslau in 1917), van der Leeuw or, later, Eliade – also included features of the 'numinous,' of the fascinating-horrifying and of the provoking (see Gentile, 2000, pp. 29–30): "The horrifying, the tremendum and fascinosum are rediscovered as aspects of religious experience." (Maier, 1996, p. 244) But Voegelin was the first theoretician, who developed systematically the pattern of 'political religions,' to describe the common grounds of modern mass movements, even if earlier ways of using the term 'political religion' are found already in Tommaso Campanella, Daniel Clasen and Christoph Martin Wieland (see Seitschek, 2003, pp. 109–120). Shortly after the publication of Voegelin's study, also other authors pointed out to the religious elements of National Socialism (see Vondung, 1997, pp. 33–34). In 1939 Kenneth Burke stated the frequent appearance of religious images and symbols in Hitler's language and called Hitler's thought pattern a perverted or caricatured kind of religious thought. Hermann Rauschning identified the roots of the National Socialist striving for world power in the Catholicity of the new belief in the Führer as embodying God. Walter Künneth interpreted National Socialism as an imitation of the Catholic Church, and Albert Camus in *L'Homme révolté* described the features of the divinization of the irrational and of National Socialist mysticism. Finally, Friedrich Heer analyzed the political 'religiosity' of Adolf Hitler as someone coming from the Austrian-Catholic milieu. In her essays, Lucie Varga had characterized National Socialism as a political religion already in 1937. Until her early death in 1941 this medievalist had dealt with the heretic movements of the Cathar and Albigenses. She wrote a number of essays, reports and a serial novel where she tried to describe and understand the atmosphere and 'religious' ideology of National Socialism. Other than Voegelin, for whom – embedded in a universal-historical theory of consciousness – National Socialism was *one* example of a gnostic mass movement or political religion, Varga was interested in concrete individual analyses which partly – like her studies on the current sociopolitical change in rural areas (Montafon Valley and Enneberg Valley) – were based on her own field research. The topic of political religion, as Schöttler points out, is basically found in all of Lucie Varga's texts, independently of her subject and her kind of discourse. More or less explicitly it is always about phenomena of conversion or identification, of orthodoxy or heresy, and not at last about those 'scapegoats' into whom in times of crisis all unhappiness can be so wonderfully projected. Outsiders, former leaders and fallen angels, heretics, witches or devils, and finally: "the Jews" (Schöttler, 1997, p. 192). When interpreting National Socialism, we may identify interesting appeals and parallels to Varga's observations, both in her husband, Franz Borkenau, and also in her friend and teacher, Lucien Febvre. Borkenau emphasized the religious dimension of National Socialism particularly in his books *The New German Empire* (1939) and 'The Totalitarian Enemy' (1940), even if – different from Varga – he never spoke of concrete religious rituals or experiences of conversion but instead of 'Nazi psychology' in the sense of a paranoid way of thinking which turned against everything and everybody (see Burleigh, 2000, pp. 3–4). Febvre asked – beyond 'intellectuality' – about the moods which came to bear by the National Socialist turnaround (see Schöttler, 1997, pp. 192–197). In 1938, also Luigi Sturzo in *Politica e Morale* had pointed out to the religious components of totalitarian movements. According to Sturzo, the entire common life is permanently mobilized by way of parades, feasts, and sports events, to create a common consciousness (*l'unanime consenso*) and to stimulate a collective atmosphere

of enthusiasm and excitement. The entire cult of the state, he says, is oriented at a leader – Hitler, Mussolini, Lenin or Stalin – who finally becomes a 'semigod.' However, he says, the thus addressed permanent mobilization of the people can only be achieved by way of a 'sfruttamento del sentimento religioso' (abusive exploitation of the people's religious feelings). Sturzo had used this formulation already in 1925. For Sturzo, a Catholic priest and the founder of the 'Partito Populare Italiana,' the separation of state and religion was the key element of the totalitarian problem. The history of modern politics, he says, is a history of the increasing idolization of the state. God is replaced by the state. It concentrates the religious feelings of its citizens, to then finally, with the help of the means of modern propaganda, exploits them for its own purposes: here Sturzo's observations are similar to Eric Voegelin's (see Schäfer, 1996, pp. 43–44). In the context of totalitarian regimes, also Waldemar Gurian spoke of 'political religion' and later of 'totalitarian religion' which, he says, is created by controlling the public opinion: "Its content is not adoration of a ruler or a dynasty but the mass which is embodied in the leader and the ruling elite. This new religion does not only demand outward participation but inner approval." (Hürten, 1996, p. 64) The post-World War I totalitarian movements – as Gurian writes in his article 'Totalitarian religions,' published in *Review of Politics* in 1952 – are fundamentally 'religious' movements striving for reshaping the nature of man and society. In this context they claim the only true and necessary knowledge of life and its meaning. According to their claim to absolute validity, everything not being congruent with their ideology must be 'cleared,' if not in reality, then at least in the people's consciousness (see Hürten, 1996, p. 68).

From Raymond Aron to Emilio Gentile

The fact that National Socialism and Communism show religious aspects or at least aspects which are similar to religion and that they employ certain ways of presentation which are related to those of the Christian Churches attracted the attention of so called 'theoreticians of totalitarianism' such as Raymond Aron or Hannah Arendt. Whereas for Voegelin, notwithstanding a strong emphasis on positive religion, after all the development of modern totalitarianism was a consequence of a vacuum due to secularization, that is the result of a decay process, for Aron who, as a university student at the University of Cologne, witnessed Hitler's rise in Germany in the early 1930s, it was due to incomplete Enlightenment. On Aron's stay in Germany as well as on his analysis of National Socialism see Aron, 1993.) For Aron, modern totalitarianism symbolized a residual of the past (see Maier, 2003, p. 14). Already in 1936 Aron hinted, as Seitschek shows (2003, p. 161), that in the case of German National Socialism he had identified religious features of totalitarian regimes. Three years later, in 1939, in a review of Halévy's *L'ère des tyrannies*, he speaks explicitly of 'political religions.' In 1941, once again he mentions the term 'political religions,' to characterize the phenomena of totalitarian mass movements. Later, from 1944 on, however, Aron speaks of 'secular religions, ' he keeps this term and reaches back to it long after the Second World War, for example in 1979, in various essays. Aron understood political or secular religions to be imitations of traditional religion and at the same time to be sharpening with increase of ideology, as Seitschek demonstrates (2003). He identified its following characteristics: firstly, making their own doctrine a dogma and reformulating the topics of their own systems into fixed tenets which finally claimed absolute truth; secondly, the concentration of power in the hands of one party or movement which in most cases culminated in an almighty, prophetic leader; thirdly, the construction of inner and outer enemies who embodied all that opposed their own, 'true' doctrines and were thus to be 'destroyed'; and fourthly, the intention to create not only a new world order but also a new kind of man. Secular religions attempt to redeem mankind but only after an apocalypse at the end of a distant future and by reshaping and restructuring society. Thus, they restructure the entire course of history in their favor by interpreting it as the embodiment of values. Modern mass propaganda help secular religions to succeed by reaching broad parts of the population, supplying them with the topics of their ideologies and thus indoctrinating them. Already in 1932, Aron saw that the masses had been stirred up by a collective belief of a religious kind – i.e., the belief in Adolf Hitler who had prophesized a chiliastic future for Germany. Later in his book *The Opium of the Intellectuals* (in French published in 1955) he dealt with the religious dimensions of Marxism, in particular with its attractiveness for intellectuals (Aron, 1957, p. 9). (Here Aron reaches back to Marx's terminology, who had called religion the 'opium of the people.' See Aron, 1957, p. 348.) In Marxism, he says, passions which otherwise would have been lived out in the religious sphere are subjected to political goals. An age of salvation is prophesized: There will be classless society, first formed by a privileged avant-garde of intellectuals. The Party as a Church includes the avant-garde and generates those dogmas that become valid also for the masses. Apart from classless society, the final goal is the creation of New Man. The doctrine of the party demands absolute obedience, the 'not-chosen-ones' being enemies who must be fought with the help of violence.

Whereas up to the 1970s Bolshevism, Fascism and National Socialism had predominantly been dealt with as political phenomena and one attempted to structure them by help of totalitarianism or Fascism theories, since then – after the Holocaust had become a focus of contemporary research – historical considerations have increasingly taken their 'religious' dimension into consideration, eventhough applying the concept of religion to political phenomena was often rejected (see Maier, 1997, p. 299). By reaching back to authors such as Eric Voegelin and Raymond Aron, one increasingly paid attention to the 'religious' elements of the National Socialist movement, worked out analogies and differences to the Christian religion and looked at the transformations of Christian topics and symbols into secular ones. Exemplarily, here we may refer to the works by Michael Burleigh, Hans Maier, Klaus Vondung, Claus-Ekkehard Bärsch, and Michael Ley (see Haring 2008: 297). In the 1990s, after the fall of the Iron Curtain, we observe not only a revival of the totalitarianism theory but also – connected, among others, to a real 'Voegelin Renaissance' – a strong research interest in the 'religious' aspects of the totalitarian movements of the twentieth century, in the context of which it is probably true that political religions as a concept or typology or type do not rule out the concept of totalitarianism

and are also not identical with it but grasp only part of the phenomenon (see Gentile, 2000, pp. 19–21). As Haring points out (2008), political 'religions' not only adopted, transformed and amalgamated the contents of Christian texts and imaginations (in the area of dogma, eschatology, apocalypse and messianism) and used Christian rites and symbols, but also fulfilled special functions for their 'believers.' One of the most important functions both of traditional religions and political religion is to evoke emotions and to give opportunities to act on emotions (see Haring, 2008a). Political religions succeed – like Eric Voegelin said – in activating people emotionally. For many authors such as Emilio Gentile their first manifestations of the sacralization of politics in the modern sense of the term are found during the American and French Revolution (see Gentile, 2000, pp. 29, 34–35), when a "political movement confers a sacred status on an earthly entity […] and renders it an absolute principle collective existence, considers it the main source of values for individual and mass behaviour and exalts it as the supreme ethical precept of public life." (pp. 18–19). (See Gentile, 2000, p. 21: "The term, the 'socialization of politics' means the formation of a *religious dimension in politics that is distinct from, and autonomous of, traditional religious institutions*." But Gentile emphasizes that "the relationship between the socialization of politics and traditional religion is, in reality, a very complex one.") And the "myth of the nation and revolutionary faith became the driving force behind the sacralisation of politics over the 200 years that followed" (p. 35). Distinguishing from the concepts of "political theology" or "civil religion" the concept of 'political religions' has steadily got more significance for the analyses of kinds of ideologies and the everyday political practice of Communism and National Socialism precisely in the past few years. To "be able to understand the mentality of that worldwide civil war: the readiness to kill and die in the service of people, class or race, 'political religion' has meanwhile become key category" (Berghoff, quoted in Albrecht, 1999, p. 10).

Political Representation

Dennis F Thompson, Harvard University, Cambridge, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The process of political representation involves relationships not only between representatives and their constituents, but also among the constituents and among the representatives. Each set of relationships raises fundamental issues of democracy and has stimulated extensive research in both normative political theory and empirical political science. One of the most notable developments is the significant expansion in the number and variety of individuals and groups who claim representation.

Political representation is a process in which one individual or group (the representative) acts on behalf of other individuals or groups (the represented) in making or influencing authoritative decisions, policies, or laws for a polity.

The representative is typically a legislator, but not exclusively. A growing body of research recognizes that a representative may hold any of a number of other offices (such as executive, administrator, ambassador, judge, lobbyist, party leader) and may even be a collectivity (a governmental agency or political organization, international as well as domestic) (Urbinati and Warren, 2008). Individual citizens themselves may act as representatives when brought together in citizens' assemblies, a relatively novel institution that has been established in Canada, the Netherlands and other countries in recent years (Warren and Pearse, 2008). There are also 'self-authorized representatives,' individuals, and organizations that do not hold official positions but have some claim to speak and act for others (Urbinati and Warren, 2008).

The represented may be almost any individual or group, but they are usually understood to be those individuals or groups, typically called constituents, who are entitled to select the representatives. As the variety and range of the represented has expanded vastly in modern times, new issues for the theory of representation have arisen (Urbinati and Warren, 2008; Rehfeld, 2005; Shapiro et al., 2010). When the constituents from several nations are represented in the same government, as in the European Union, the question of who is to be represented becomes especially problematic (Thompson, 1999; Kroger and Friedrich, 2012).

The process of representation involves relationships (1) between the representatives and the represented, (2) among the represented, and (3) among the representatives. With respect to (1), the issue was once framed as a dichotomy between delegate and trustee conceptions of representation – whether representatives follow their own judgment or their constituents' preferences. But it is now recognized that the dichotomy is too simple and the literature distinguishes many different modes of this relationship (Pitkin, 1967; Thompson, 1988; Rehfeld, 2009).

As for (2), the key question concerns the criteria by which constituencies are defined (Rehfeld, 2005). Although many different criteria (including gender, ethnicity, religion occupation, and class) have been proposed and applied in various systems, the most common in modern electoral systems are party and geography. One of the most fruitful but controversial areas of inquiry raises issues of representation of identity groups of various kinds (Williams, 1998).

With respect to (3), scholars now recognize that the interactions among representatives are no less important than the linkages between representatives and constituents, which tend to receive the larger share of scholarly attention (Thompson, 1988). The increased polarization, especially in the US Congress, and the decreased capacity for compromise have prompted several new lines of research (see Section The Performance of the Representative Body below).

Origins and Development

Political representation arose not as a democratic but as a monarchical and aristocratic practice in medieval government in Europe. Both the theory and practice evolved over a long period from about the fourteenth to seventeenth century as kings and nobles convened assemblies to collect revenue and conduct wars. The bodies, usually composed of members from various estates or classes, gradually assumed independent power and came to be thought of as representative institutions. In the debates during the Civil War period in England, defenders of Parliament connected the idea of representation to the idea of consent of the governed. In 1651, the members of Parliament were for the first time referred to as 'representatives' (Pitkin, 1967; also see Larsen, 1966; Manin, 1997).

By the eighteenth century, the link between representation and popular rule (though not democracy) had become sufficiently close that Baron de Montesquieu could praise the English constitution for establishing a republic in a large state by giving the people a voice through their representatives in the legislature. Defending the new American constitution, James Madison argued that representation not only made republics possible in large territories, but also mitigated their dangers, especially the influence of factions. It was John Stuart Mill who in the late nineteenth century provided the framework for the theoretical synthesis that combined the traditional virtues of representation and the emerging ideals of democracy (Thompson, 1976).

Representative government was not yet representative democracy, because much of the adult population neither served as a representative nor counted as the represented. The practice – notably the expansion of franchise that is essential to

making representation democratic – lagged behind the theory. Universal suffrage came slowly and fitfully in the United States. Barriers to participation and biases in influence persist today. Even the so-called advanced democracies cannot yet claim to be inclusively representative. Furthermore, as the scope of government has expanded and the interactions among societies increased, many people are affected by the actions of governments over which they have no formal control or practical influence. Despite its elitist origins and democratic deficiencies, representation is now defended as a valuable component of democracy (Urbinati, 2008).

The Role of the Representative

The relationship between the representative and the represented is usually analyzed in terms of the role of the representative. It is sometimes called dyadic representation to differentiate it from the more complex relationship that exists between all representatives in the legislature and the electorate or public as a whole (Ansolabehere and Jones, 2013). (Compare 'dynamic representation': Stimson et al., 1995).

Three aspects of the role of the representative should be distinguished. The first concerns the *mode* of representation – how constituents are represented. To what extent does a representative express the views of constituents, attempt to change their views, and by what methods and over what time periods? The second aspect is the *locus* of representation – which citizens are regarded as constituents by the representative? (This aspect involves the identification of the represented.) Among the possibilities are the nation as a whole, a political party, the state or district, and various groups and organizations. The district is more complex than often assumed. For example, many legislators are bound to local elites and national groups whose interests may diverge from those of other individuals and groups in the district; some legislators see themselves as representatives of underrepresented groups, such as blacks and women. The third aspect refers to variation in the *content* of representation – the types of issues with which a representative deals. A legislator may act, for example, as a delegate of the district majority on welfare issues, as a delegate of the national majority on civil rights, but as a trustee of both on foreign policy.

Much of the empirical literature on the linkages between the policy preferences of constituents and legislators has been influenced by the seminal model presented by Miller and Stokes (1963), which highlights four major variables: legislators' personal attitudes, roll call votes, constituency opinion, and legislators' perceptions of constituency attitudes. The vast literature on this linkage shows that the conditions under which each has an effect are quite variable. It is now recognized that roll call votes fail to capture much important legislative activity and do not always reflect the actual views of legislators.

Given this complexity, it is not surprising that most normative theories today decline to privilege any one of the aspects of the roles: what each representative should do depends on the nature of the particular issues, what other representatives are doing, and the biases in the political system. Some of the most interesting normative work is revitalizing the ethics of representation (see Dovi, 2007; Beerbohm, 2012). Similarly, when political scientists examine the simpler conceptions of role, they find little general correspondence between the role and actual behavior. The most robust accounts of legislators' conceptions posit decision trees with multiple branches and a complex set of factors (Kingdon, 1981; Thomassen, 1994). In some legislatures, such as Congress, representatives specialize in particular issues and in effect delegate their decision-making to other representatives (Hall, 1998).

On any account of the role of the representative, there is the further question of how representatives can be held accountable. For Congress, Mayhew's model, which posited that representatives are motivated solely by the desire for reelection, dominated the literature for many years (Mayhew, 2004). The 'electoral connection' has been shown to explain much of the behavior of members of the House, and in modified form can be seen in earlier periods in American history as well (Carson and Jenkins, 2011). But the resurgence of partisanship and party control in recent years stands in tension with Mayhew's insistence that individual members, not parties, are the most significant unit of analysis (Aldrich and Rohde, 2001).

Beyond the United States, the methods of accountability vary depending on the political system and on assumptions about what political accountability means (Przeworski et al., 1999). There has been an 'explosion' of comparative studies that examine representational linkages in many different countries (Powell, 2004).

Since at least the eighteenth century students of legislatures have criticized the influence of money and wealth on the behavior of representatives. Concern about this influence has increased in recent years, especially in the United States. As reformers have called attention to the problem, researchers have devoted more attention to its causes and potential remedies (Lessig, 2011; Francia et al., 2003). Political scientists have not generally found strong correlations between contributions and roll call votes on broad policy areas even in the US system. But they have found that money can buy access – marginal time, energy, and legislative support (Hall and Wayman, 1990). The increasing availability of data in other countries has led to a growth in comparative research on the role of money in politics (Scarrow, 2007).

The Identification of the Represented

All legislative representation is group representation. Even in societies governed by individualist norms such as 'one person-one vote,' the definition of the constituency implicitly identifies a group or groups that are to be represented. Electoral rules and other features of the political system shape the relative weights of various groups in the representational process.

One major line of research takes parties as the main unit of representation and measures representativeness by the ratio of legislative seats to votes (Powell, 2004). Proportional systems have been found to translate seats into votes most accurately (and presumably more fairly). In the most common forms, the share of votes that each party receives determines how many of the candidates from its list win seats in the legislature. The system usually produces multiple parties, and thus gives voters a wide range of ways to express the interests they wish to have

represented. However, it also gives voters less choice about which particular candidate should serve as their representative, and in this respect differs significantly from the purer form of proportional representation, the system of the single-transferable vote, in which every successful candidate has a unanimous constituency. Because the more common forms of proportional representation rarely produce majority governments, much of the research considers how the strategies of coalition building and party discipline affect representation (Martin and Vanberg, 2011).

Geographical representation relies more on single-member plurality systems and tends to produce only two or three parties. The parties represent broader interests than do the parties in modified proportional systems, but if party discipline is weak, as in the United States, the geographical basis encourages the representation of particular regional and other interests.

No single type of representational system has been shown to be superior in all or most circumstances, and the choice generally involves a trade-off: the wider the range of interests represented in the legislature, the less the likelihood that any particular interest will be fully represented in legislation actually adopted. The most useful scholarship on these and related questions has been comparative (Norris, 2004; Farrell, 2011).

Another important line of research begins with citizens' preferences rather than with their votes, and compares their policy views to those of their representatives (again typically by party). This research begins with the Miller–Stokes paradigm but moves from the dyadic relationships (individual representatives/groups of constituents) to analyze the electorate as a whole in relation to the legislature or the legislative party (Powell, 2004). One of the most striking findings is that citizens are generally more divided than their representatives. That means that there are some voters in each party who favor positions that are supported exclusively by representatives of other parties. In this respect, a party cannot be considered as the primary form of representation, at least for these citizens (Holmberg, 2000).

In systems such as the United States, where many of the districts that define constituencies do not follow any natural geographical boundaries, the questions of how the districts are drawn and whether they produce fair representation have stimulated important normative and empirical research. Political scientists have examined the partisan and incumbency biases in various redistricting schemes (Bullock, 2010). Some of the most valuable theoretical work in this area combines empirical and normative approaches. One study has developed more analytically robust concepts of 'fair representation' in electoral systems (Beitz, 1989), and another has revived the theory of descriptive representation for 'marginalized groups' (Williams, 1998). Scholars have investigated to what extent descriptive representation supports substantive representation by studying the presence of women in parliaments (Wängnerud, 2009).

Several important studies have shown that representation (not only in the legislature) is increasingly biased in favor of wealthy constituents and corporate interests. The phenomenon is most salient in the United States. (Bartels, 2008; Hacker and Pierson, 2011; Gilens, 2012). However, a growing body of research is finding that other systems are showing similar patterns (Beramendi and Anderson, 2011; Lefkofridi et al., 2012). The causes of the inequality, and the appraisal of its effects, remain controversial. Scholars investigating what is called dynamic representation casts doubt on whether the representation is unequal in any way that should be objectionable. They find that the views of groups move in parallel, shifting left or right more or less together, and that, because representatives follow the shift, groups are treated equally. Stimson (2011) argues that this apparent conflict can be resolved if we recognize that within the broad left and right shifts, the modest biases toward the wealthy accumulate over time and produce gross inequalities in the effects of policies.

The principle that 'everyone who is affected by the decisions of a government should have the right to participate in be represented in that government,' though not without problems, is widely accepted in democratic theory and practice (Goodin, 2007). Yet it has potentially radical implications for representation in an increasingly interdependent world. As the effects of government policy spill over national boundaries, the principle and related criteria would seem to require granting some form of representation to individuals who have not traditionally been included as part of the represented. This line of thinking has led, for example, to research on new forms of accountability in environmental policy (Mason, 2008).

As national boundaries become more porous, the representation of noncitizens and expatriates has also become a more pressing issue. The debate about this issue, conducted under the rubric of transnational citizenship, focuses on enfranchisement of the residents who are not citizens and citizens who are not residents (Lopez-Guerra, 2005; Owen, 2011). More generally, scholars urge that more attention be given to what has been called 'moral constituents' – not only individuals such as foreigners who are affected by decisions in which they have no formal voice, but also future citizens who cannot be formally represented because they do not yet exist (Gutmann and Thompson, 1996; ch. 4; Thompson, 2010).

The Performance of the Representative Body

Much of the research on the relationships within legislatures and other representative bodies deals with the tension between individual and collective behavior in the legislature. The general problem concerns what is sometimes called legislative individualism, which includes the tendency of legislators to act in ways that promote their own goals without regard to the effect on collective product of the legislature (Corey, 2008). This tendency has been shown to produce a surplus of 'particularized benefits' (dams in certain regions, tariffs for local industries, and military bases in the district) and the neglect of more general public benefits (such as education, health, and the environment (Evans, 2013)). The explanations for these outcomes vary, but they are generally structural, locating the problem in the incentives of the system, rather than in the character of legislators (e.g., Crisp et al., 2004). They assume that, given the structure of the political system, individually rational behavior by legislators produces collectively suboptimal outcomes in the legislature.

If all legislators are pure individualists seeking only particularized benefits for their own constituents, how (under

conditions of majority rule and weak parties) can the legislature adopt any legislation at all, even the pork barrel kind? This puzzle has been studied by formal theorists, who propose various solutions for achieving policy equilibria in legislative institutions (Shepsle and Weingast, 1995). One solution relies on a committee system to set an agenda and limit the scope of conflict.

Shared interests and cross-cutting cleavages are still prevalent in any actual system. These are more likely to exist or to arise in legislatures that encourage or at least permit representatives to change their positions through interaction with their colleagues. This is claimed to be one of the advantages of deliberative theories of legislative representation, which allow for changes in the preferences of both representatives and the represented over time (Gutmann and Thompson, 1996). Political scientists have begun to conduct empirical studies to learn how deliberative democracy actually functions in legislatures (Steiner et al., 2004).

In the United States, the increasing polarization of Congress has drawn the attention of scholars because it is thought to be one of the causes of the deadlock and dysfunction, many ascribe to the institution in recent years. Political scientists disagree about the source of the polarization itself. Is it only elites who have become more polarized, or also the electorate? and if both, to what extent are representatives the cause? (Fiorina and Abrams, 2008; Abramowitz, 2010). The challenge of governing in a polarized legislature has revived interest in the classic problem of political compromise (Gutmann and Thompson, 2012).

Political Repression

Abstract

Political repression continues to be a harsh reality in many states today. A large body of empirical literature seeks to understand why states imprison, torture, force disappearance of, or kill their own citizens. The empirical literature has demonstrated that several factors are associated with decrease in political repression; the most significant being domestic threat, especially civil war. Other factors are associated with increased repression; the most consistent being the level of democratization achieved within the state. The research suggests that commitment to rights through treaties and constitutional provisions, especially in tandem with an independent judiciary, may be one potential path to lessen repression, as is the role of international NGOs in the state.

Political repression by one's own state continues to affect almost half of the global set of countries today. For example, citizens in almost 60 countries live in a state with extensive political imprisonment, unlimited detention, and extrajudicial executions or other political murders and brutality. In more than 30 other countries, political murders and disappearances are a common part of life and may affect even those who are not politically engaged. Over the last two decades social scientists have produced a growing body of studies that systematically and rigorously examine theoretically important factors that may explain why states politically repress their own citizens. The empirical study of political repression focuses on two categories of state abuse of human rights and typically involves the creation and dissemination of large cross-national datasets that encompass the global set of countries and increasingly longer periods of time. Political repression is broadly defined as "involving the actual or threatened use of physical sanctions against an individual or organization, within the territorial jurisdiction of the state, for the purpose of imposing a cost on the target as well as deterring specific activities and/or beliefs perceived to be challenging to government personnel, practices or institutions" (Davenport, 2007b: 2). Most of the literature focuses on one of two forms of political repression separately – either addressing the more severe form of repressions, namely violations of personal or physical integrity (imprisonment, torture, killing, and disappearances) (e.g., Poe and Tate, 1994; Poe et al., 1999) or addressing the broader category of civil liberties restrictions that are typically of less severe form (e.g., Davenport, 1995). While the theoretical perspectives on the two forms of repression are largely indistinguishable, the most comprehensive examination of both categories of repression shows that while they are similarly influenced by the same agentic and structural factors, significant differences emerge with regard to the influence of domestic and external threats, an independent judiciary and constitutional provisions (Keith, 2012). Henderson (2004) makes an important contribution in expanding the traditional conceptualization and measurement of political repression to forms that are specifically targeted at females, which includes such acts as harassment, degrading treatment, denial of sanitary devices for women's hygiene, virginity examinations, hostage taking to pressure male family members, imprisonment with men, absence of female guards, threats of rape, actual rape, forced prostitution, and pregnancy.

Measuring Political Repression

Social scientists seeking to empirically measure state repression face significant measurement issues, but over time political scientists have developed several measures that capture the level, frequency, and type of political repression. Most empirical studies to date have primarily addressed the most severe form of repression – violations of personal integrity (e.g., Poe and Tate, 1994; Poe et al., 1999; Cingranelli and Richards, 1999; Keith, 2002a) – and have tended to employ the dominant indicators in the field, for example, the Political Terror Scale (PTS) which is maintained by Gibney et al. (2014) (www.politicalterrorscale.org) and is a standards-based measure of state use of political imprisonment, torture, killing, and disappearances that is operationalized as a five-point ordinal scale that ranges from one, where repression is rare, to five where repression is extensive and threatens the entire population. **Figure 1** shows the percentage of countries at each level of political repression over time. We see a significant proportion of states achieving a score of one, the lowest level of repression or no repression, which ranges from 25 to almost 35%, with a significant drop following 2001. The proportion of countries with the highest level of repression (five) represents the smallest segment of countries, ranging from 2 to 12.5%. Level four of repression represents the second smallest segment here. We see the mid-levels of repression (two and three) affect approximately the same percentage of states over time as the lowest level of repression, with some variation over time. With the addition of a new measure, the CIRI physical integrity measure, which is maintained by Cingranelli et al. (2013) (www.humanrightsdata.org), empirical studies can now examine the same four behavioral components individually or as an additive index. Some limitations and benefits adhere to each of these measures (see http://www.politicalterrorscale.org/datafiles/hrq%20pts.pdf); most scholars deal with the trade-offs by conducting parallel analyses employing both measures. Conrad and Moore's (2014) new Ill-Treatment and Torture (ITT) measures, while focusing on a single dimension of repression of personal integrity rights (torture), offers

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93178-7

Figure 1 Political repression of Personal Integrity Rights, 1979–2005.

significant advantages over both the CIRI and PTS measures, in which it includes indicators related to the agents of torture, the victim type, and the level of torture (http://faculty.ucmerced.edu/cconrad2/Academic/ITT_Data_Collection.html).

Measuring the level of state restrictions on civil liberties has proven to be more difficult. The two earliest popular measurements of political repression, Taylor and Jodice's (1983) state coercive behavior and Freedom House's civil liberties index (http://www.freedomhouse.org/report/freedom-world/freedom-world-2014#.Uyh57vldX-o), represent significant data collection efforts, but each of them has significant limitations. Taylor and Jodice's measurements are events counts that are limited in country and time coverage. The construction of the Freedom House's civil liberties measure is unclear and the two of its four core components are problematic in that they do not specifically examine civil liberties protection per se, but rather measure circumstances and institutions that may facilitate or hinder the protection of civil liberties or deal with the abuse of these rights which would appropriately be classified as oppression of social and economic privileges falling outside the definition of repression above. Scholars now have access to new standards-based measures within the CIRI data project mentioned above that allow them to examine separately some core individual liberties such as freedom of religion, speech and press, and assembly and association. While the range of civil liberties they cover is limited and the pairing of rights is not theoretically intuitive, the measures do not suffer from many of the shortcomings of the Freedom House measure. **Figure 2** presents the mean repression scores for CIRI's freedom of speech and press, freedom of assembly and association, and freedom of religion measures. As with most studies, I have inverted the CIRI measures here to reflect repression of these freedoms, thus each of the three measures is now a three-point scale that ranges from zero to two with zero representing no repression and two the highest level of repression. We see several interesting trends. First, the most obvious pattern is that repression of religious freedom is consistently higher than repression of the other two sets of freedoms, and while there is some variation over time, there is virtually no improvement in the entire time period. Indeed in 2005 we see a higher mean of repression than the beginning date of 1981. Second, we see a clear improvement in the level of repression for the other two categories of freedom, beginning with the end of the Cold War and leveling off in the mid-1990s with an increase in repression of speech/press beginning in after 2001, which could be related to the shift in emphasis to national security priorities following September 11. We do not see the same pattern, however, for freedom of assembly and association, which during most years is repressed less than speech and press freedoms.

Dominant Theoretical Approaches to Understanding Political Repression

Most of the current empirical work on political repression has approached the state's behavior from the perspective of international relations theory, primarily utilizing a 'soft' rational choice perspective (e.g., Poe et al., 1999; and Davenport, 2007a) that assumes that political leaders are rational actors and that they choose from a menu of repressive tools because they perceive these tools to be the most effective means to

Figure 2 Mean repression of freedom of speech and press, freedom of association and assembly, and freedom of religion.

achieve their chief end, which is to stay in power. The most pervasive factor that increases leaders' willingness to employ the tools of repression is a threat to their rule, whether real or perceived, and that typically the more serious the perceived threat, the more willing state leaders are to employ repression (Keith and Poe, 2004; Keith, 2012). Or more broadly, as Davenport argues, state actors utilize actual or threatened physical sanctions in order to impose "a cost on the target as well as deterring specific activities and/or beliefs perceived to be challenging to government personnel, practices or institutions"; however, state actors carefully weigh the costs and benefits of engaging in repressive action, and also consider a menu of alternative mechanisms of control, as well assessing the odds of achieving their goals with these tools (2007a: 2–4).

The repression literature has drawn upon the theoretical insights of the domestic institutions/democratic peace perspectives – another stream within the rational actor approach. However, these perspectives dismiss the assumption of a unitary state actor and instead recognize the role of numerous domestic actors and institutions within the state (particularly in democratic regimes) which may affect the regime's menu of acceptable policy options and/or the regimes' calculation of costs and benefits related to commitment to international and national human rights norms and with subsequent (non)compliance to formal commitment to the norms. Poe et al. (1999) argue that state leaders in democratic regimes have less opportunity and less willingness to employ the tools of repression, even when facing domestic or international conflict or threats (293, and citations within). Opportunity is constrained because the structure and limited nature of democratic governments, which may include separation of powers and/or checks and balances, make it difficult for state actors to coordinate extensive use of repression. The necessity to utilize repression as a tool to solve conflict can be mitigated in democracies because they provide a variety of alternative mechanisms through which conflict can be channeled for possible resolution (Poe et al., 1999; Davenport, 2007b), in turn, weakening the state's justification for coercive state action. In addition, the need to employ the tools of repression is also dampened by "the socialization processes that guide citizens of democratic polities toward the belief that nonviolent means of resolving conflicts are preferred over violence" (Poe et al., 1999: 293). The democratic norms of compromise, toleration, and facilitation may influence the decisions of the rulers by "increasing the cost of human rights violations as well as decreasing the value to quiescence" (Davenport, 1999: 96). The cost of repression is increased in democracy as the electoral process "provides citizens (at least those with political resources) the tools to oust potentially abusive leaders from office before they are able to become a serious threat" (Poe and Tate, 1994: 855). From the domestic legal institutions perspective it is not just democratic electoral processes, but also the legal institutions associated with democratic systems that can provide the public and other political actors the tools and venues through which they can hold the regime accountable, should it fail to keep its formal commitments, both domestic (Keith, 2002: 2012) and international (e.g., Powell and Staton, 2009). A truly independent judiciary, in particular, "should be able to withstand incursions upon rights because (1) the courts' power and fiscal well-being are protected, (2) the courts have some ability to review the actions of other agencies of government, and (3) the judges' jobs are constitutionally protected" (Keith et al., 2009: 649). Powell and Staton (2009) posit that in states where the courts are influential (effective),

the use of repression may lead to rights claims in which the regime will incur a loss of resources as punishment for violating its obligations (154).

Another set of theoretical approaches generally focuses on transnational or international interaction and socialization which is believed to drive the creation of and commitment to international human rights norms, rather than rationalist calculations. These perspectives emphasize the transformative power of international normative discourse on human rights and the role of activism by transnational actors (international organizations and nongovernmental actors) who through repeated interactions with state actors induce states to accept new norms and also support local efforts to press for human rights commitment. Thus, their emphasis is on the processes through which state actors adopt formal constraints on the state's opportunity to repress and through which state actors eventually internalize international human rights norms or values which over time removes many of the tools of repression from the state's menu of appropriate policy options. The transnational advocacy networks posits that international human rights norms are diffused through networks of transnational and domestic actors who "bring pressure 'from above' and 'from below' to accomplish human rights change" (Risse and Sikkink, 1999: 18). A second perspective, the world society approach (e.g., Meyer et al., 1997) perceives states to be embedded in an integrated cultural system that "promulgates cognitive frames and normative prescriptions that constitute the legitimate identities, structures, and purposes of modern nation-states" (Cole, 2005: 477). Thus, with the proliferation of human rights treaties codifying human rights norms, states' legitimacy, or 'good nation' identity is increasingly linked to the formal acknowledgment of these norms and newly emerging or independent states will be likely to adopt standardized forms of government (Go, 2003). However, as Cole notes, many states join the traditionally weak human rights regime, "not out of deep commitment, but because it signals their probity to the international community" and thus "a decoupling is endemic to the human rights regime" (p. 477).

Empirical Findings

Standard Model

While much of the early repression work was quite thin in terms of applying broad theoretical approaches, as Davenport and Armstrong (2004) note, over time a 'standard' model has emerged in the repression literature (Poe and Tate, 1994; Poe et al., 1999 and the numerous citations within) that includes nine variables: level of democratization, which is discussed separately in the following sections; two forms of threat (civil war and international war), which are also discussed in the following sections; two additional regime types (military and leftist regimes); and socio-economic conditions (economic development, population size, and colonial legacy). All of but one of the variables within the model represent the domestic environment of the state that either constrains or creates the regime's opportunities to repress or that affects the regime's decision-making calculation of the advantage or disadvantage to exercising repressive tools as a means to achieve its policy goals. Over time the body of empirical work has expanded beyond domestic influences to examine a variety of international or transnational influences, including bilateral aid, multilateral lending programs, international treaty regimes, trade relations, and foreign investments. As the models of repression have expanded, the latter five variables of the standard model above have performed inconsistently. And while they continue to be used as control variables, other variables have become more theoretically and statistically important.

Democracy

Democracy is the most widely tested and consistently performing variable in the standard model. While the literature has tended to assume a linear association between the level of democracy and repression, recent theoretical and empirical work suggests that this oft unstated assumption does not accurately reflect the true relationship between democracy and repression. In more recent work, Davenport and Armstrong (2004) as well as Bueno de Mesquita et al. (2005) argue and demonstrate empirically that the relationship between democracy and repression has been misspecified and that a threshold effect is a more accurate characterization. Other scholars have perceived democracy as a multidimensional concept and have found that some dimensions of democracy are more likely to lessen the use of political repression – most particularly, the competitiveness of political participation (Keith, 2002a; Bueno de Mesquita et al., 2005).

Domestic and External Threats

Theoretically, the most significant factor is the presence of domestic opposition or a perceived challenge to the regime's hold on power, especially if there is a threat (actual or perceived) that the regime's challengers may resort to violent tactics. The regime may choose to employ coercive force to prevent, contain, or punish such threats. The most potentially disruptive form of domestic threat, civil war, has received the most empirical attention, and its effect has been demonstrated to be the strongest of many factors, in terms of impact, statistical robustness, and consistency across a variety of measures of repression and other human rights behavior. To illustrate the magnitude of its impact, Poe et al. (1999) demonstrate that an ongoing civil war would increase the level of repression over time by around one and half points on a five point scale of repression, with other factors in the model held equal (p. 308). The literature has also sought to understand the impact of less severe forms of threat, as well as other dimensions of threat, such as the variety of strategies and frequency of conflict. For example, Davenport (1995) found that deviance from past norms of conflict, the frequency of conflict, and the variety of strategies engaged, each increase the likelihood that a state would resort to civil liberties restrictions; however, once these factors are controlled the presence of domestic violence becomes statistically insignificant. Poe, Tate, Keith, and Lanier (2000) found that the repressive response to domestic threats was dependent not only on the level of the threat but also upon the prior level of repression. Regan and Henderson (2002) also found that the level of threat was positively associated with repression, and that the impact of threat was greater than that

of regime type. External threats are also theoretically important, and the empirical literature has consistently confirmed the effect of international war participation on domestic political repression, and thus over time, international war has become a key component of the standard model of human rights behavior (Poe and Tate, 1994; Poe et al., 1999; Cingranelli and Richards, 1999; Davenport and Armstrong, 2004); however, the impact of international war is substantially lower than that of civil wars. For example, Poe et al. 1999 found the impact of participation in a civil war to be at least three times the impact of being a participant in an international war. This is somewhat intuitive even though external threats such as interstate war are potentially more serious than civil wars, often civil wars are a greater threat to regime due to the proximity and ability of the opposition to impose damage, especially compared to some interstate wars, which may be fought far away from at least some of the belligerents' states, such as in the Persian Gulf War or the War in Iraq.

Domestic Legal Commitments and Institutions

A growing body of research has examined the question of whether constitutional provisions for rights and an independent judiciary constrain the likelihood of states repressing their own citizens. Most of these studies have examined the role of specific rights, typically imbedded bills of rights (e.g., Davenport, 1996; Keith, 2002a; Keith et al., 2009; Keith, 2012) and to a lesser extent have examined institutional constraints such as provisions for an independent judiciary (Blasi and Cingranelli, 1996; Keith, 2002b; Keith, 2012), states of emergency clauses (Keith and Poe, 2004; Keith, 2012), or provisions for federalism (Blasi and Cingranelli, 1996). Most of the earliest analyses found evidence that not only were the constitutional rights provisions not associated with improved rights behavior, the associations were in the opposite direction, suggesting a harmful effect. As studies have improved in their temporal and spatial dimensions and have become more sophisticated methodologically, the observed effect of constitutional rights provisions has become somewhat more consistent and suggests a beneficial effect overall. The effect of constitutional provisions for judicial independence appears to be more appropriately conceptualized as influencing *de facto* judicial independence, which in turn consistently decreasing the probability of repression of all forms (Keith, 2012). One set of constitutional provisions remains problematic – studies have consistently argued and demonstrated that certain provisions for states of emergencies (such as derogation clauses), which have been promoted by international organizations such as the International Lawyers Association and International Commission of Jurists, have unintended consequences and are largely associated with increased levels of repression.

International Treaties, Norms, and INGOs

Measuring norms is probably the most difficult task that empiricists face in testing normative approaches, and thus most empirical studies of compliance have examined surrogate indicators. Following Goodliffe and Hawkins' (2006) work on treaty commitment, Keith et al. (2009) use regional and global commitment rates to the International Covenant on Civil and Political Rights (ICCPR) as measures of norms, but find no effect in a variety of models of repression. Powell and Staton (2009) test regional and global norms, as indicated by past rates of torture, in their Convention Against Torture (CAT) models; however, they find too little evidence that norms influence state torture practices. Most empirical studies of state compliance with international human rights treaty obligations focus on the state's provision or protection of the guaranteed rights embedded in the document. The bulk of the empirical compliance literature, while grounded in rich theoretical debate concerning the influence of human rights treaties, has largely been limited to tests of whether being a state party produces a positive or negative effect, controlling for a variety of factors. It does not enable us to determine which of the mechanisms that are hypothesized to be at work are actually operative. While the literature examines a broad range of human rights behavior, much of the research has focused on rights abuse that would appropriately be labeled as political repression. Extant empirical evidence of influence of participation in the international human rights regime has been rather mixed. For example, Keith (1999) finds no effect from the ICCPR on either form of political repression, unless controlling for state derogations. Hathaway (2002) finds that most treaties within the human rights regime do not significantly affect human rights behavior, and that participation in some of the treaties, such as the CAT produce negative effects, a result which is confirmed by Hafner-Burton and Tsutsui (2005) in regard to a wide range of treaties. On the other hand the most exhaustive compliance studies (Landman, 2005) found consistent evidence of an association between rights behavior and state commitment to a variety of treaties within international human rights regime. Landman finds that commitment to the ICCPR and the CAT, even while controlling for the level of reservations decreased state repression of personal integrity rights, torture, and civil and political rights. On the other hand, Hill's (2010) sophisticated analysis of the CAT and the ICCPR, finds both to be associated with increased repression. Keith's (2012) comprehensive analysis of both forms of political repression (and a variety of measures), found that the ICCPR has both a beneficial unconditional effect and an interactive effect with international NGOs (INGOs); however, the Optional Protocol to the treaty, only has an effect in conjunction with the presence of INGOs. The CAT has neither conditional nor unconditional effect on any form of repression, regardless of measures. Thus, our understanding of international treaties' ability to reduce repression remains sketchy.

The presence of transnational networks or civil society pressure (typically measured as the number of INGOs in which citizens have membership) is much easier to measure than the presence of norms; however, the direct link between treaty ratification and civil society pressure is not typically tested in human rights models. Both Hafner-Burton and Tsutsui (2005) and Powell and Staton (2009) find that as the number of INGOs to which citizens belong increases, the level of protection of human rights increases. Neumayer (2005) provides the most rigorous analysis, examining specifically the effect of treaty commitment on human rights behavior, conditioned upon the strength of civil society organizations. However, his results are rather mixed: he does find that the stronger the state's participation in INGOs the greater the beneficial effect of

ratification of the CAT on human rights behavior; however, the results do not hold for ICCPR ratification. He also finds mixed results in regard to regional treaties. For example, while the benefit of ratification of the Inter-American torture convention increases as INGO participation increases, the effect does not hold for the European torture convention.

Overall, the observable effect of norm diffusion is rather weak and inconsistent at best. The evidence of a strong positive influence by NGOs on states human rights practices is more convincing; however, we must keep in mind that the civil society linkage through treaty ratification is not directly demonstrated except in Neumayer's work. The evidence of the beneficial effect of treaty commitment continues to grow with more sophisticated and rigorous analyses, with the exception of the CAT, which has no observable benefit.

Bilateral, Multilateral, and Global Economic Influences

As the field has grown over time, increasing attention has focused on bilateral, multilateral, and global economic influences. While much attention has been given to impact of repression on bilateral aid allocation, relatively little attention has been given to the question of whether U.S. aid influences human rights practices of recipient states (e.g., Shoutlz, 1981; Regan, 1995; Apodaca, 2001) beyond the two studies supported by USAID itself (Finkel et al., 2006, 2008) and by Knack (2004), by a senior research economist for the World Bank who examined the impact of western foreign assistance on democratization in recipient states. While there are strong theoretical links between aid and improved human rights practices, both direct and indirect, there is also some justification to expect that aid would not influence human rights or that it might even have a harmful effect. Overall, the empirical evidence suggests that bilateral aid has limited (Regan, 1995; Apodaca, 2001) or no effect (Knack, 2004), and sometimes a harmful effect (Shoultz, 1981). Two comprehensive analyses of the USAID democracy and governance aid commissioned by the USAID itself have consistently demonstrated that while spending in the other subsectors of aid (elections, civil society, and governance) all produce the desired effects, spending on the human rights component of the rule of law program has a strong negative effect on states' human rights protection, regardless of numerous controls, including controls for endogeneity, and regardless which measure of human rights is employed (Finkel et al., 2006, 2008). As the investigators note in the final report of their second study, their "effort to untangle the web of relationships that may underlie this distressing and presumptively anomalous relationships and to model them statistically has been largely unsuccessful in its basic purpose" (Finkel et al., 2008: 57). While scholars seem somewhat reluctant to expect these null or negative findings, we are left with the dilemma that aid may actually promote political repression, at least under some circumstances. Recent empirical studies of the influence of multilateral aid programs have been just as pessimistic. A growing number of empirical studies have demonstrated the IMF structural adjustment programs lead to increased repression. The most comprehensive and rigorous study to date (Abouharb and Cingranelli, 2008) demonstrates that the structural adjustment programs of both the IMF and World Bank increase civil conflict which in turn increases the state's level of physical integrity. The evidence in regard to global economic influences, such as trade openness and foreign economic penetration is mixed but somewhat more optimistic than that of the aid relationship.

Empirical studies that have tested liberal economic theory on the link between trade and human rights protection, although small in number, have consistently confirmed these expectations (e.g., Apodaca, 2001; and Harrelson-Stephens and Calloway, 2003). The evidence examining the effect of foreign investment has been much more inconsistent, often dependent upon the category of repression with FDI reducing only the likelihood of political repression of civil liberties not the personal integrity (Apodaca, 2001; Richards et al., 2001). Keith's (2012) more comprehensive study of a three-decade period consistently found that all indicators of global embeddedness (trade, FDI, and WTO membership) were associated with increased odds of both forms of repression. Overall, the effect of bilateral and multilateral aid, as well as those of global economic influences, proves consistently to be in a direction that is harmful to human rights, and to increase the likelihood of repression.

The Future of Empirical Study of Political Repression

Several limitations across the literature suggest the direction for future research. While the theoretical approaches that have informed the empirical examination of state repression has expanded to draw a wider range of disciplines, an integrative grand theory is yet to evolve. And while the reification of the state as a unitary actor has faded somewhat with the integration of the domestic institutions approaches, the empirical literature continues largely to ignore the individual, actual agents of the state (or private actors sanctioned by the state) who directly engage in the human rights violations. This lack is likely linked, in part, to severe data limitations that restrict the growth of the field. For this body of research to progress, social scientists must create data that move the temporal dimension of the data beyond the arbitrary calendar year. These finer delineations are necessary to capture the response of states to particular events, especially in terms of perceived threats to the regime. In addition, scholars need to follow the lead of Conrad and Moore and create variables that identify the state or state-sanctioned actors (and their relevant characteristics) who engage in or facilitate repression, and similarly, variables that identify the targets of repression. Finally, scholars should move toward capturing a more nuanced understanding of the modalities of repression, especially in regard to the variation in legality. This improvement would allow scholars to examine the substitutability of tools of repression.

Abstract

This article describes a framework for the Empirical Implications of Theoretical Models (EITM) initiative. The objective of EITM is to encourage political scientists to test and estimate empirical models that are directly connected to an analytical model. The practice of merging formal and empirical analysis can reduce nonfalsifiable research and acquire social scientific accumulation. The EITM framework can be considered a three-step procedure. The first step is for researchers to unify theoretical mechanisms and applied statistical concepts. Step two is to develop measurable devices ('analogs') for these mechanisms and concepts. The final step is to unify the analogs. Using a set of plausible facts or axioms, scholars can build a rigorous mathematical model to potentially identify causal relations that explain empirical regularities.

Introduction

Background

In July 2001, the Political Science Program at the National Science Foundation (NSF) convened a workshop seeking ways to improve technical–analytical proficiency in Political Science. (The 2001 NSF EITM Workshop was recorded and transcribed. The written transcript is available on the NSF Political Science Program Web Site: www.nsf.gov/sbe/ses/polisci/reports/eitm709.pdf and www.nsf.gov/sbe/ses/polisci/reports/eitm710.pdf. A report of the EITM initiative (EITM Report 2002) is also available at: www.nsf.gov/sbe/ses/polisci/reports/pdf/eitmreport.pdf.) The workshop, termed the Empirical Implications of Theoretical Models (EITM) Workshop, suggested constructive approaches so that the NSF Political Science Program could develop linkages between formal and empirical modeling. (A quantitative model can be characterized as a construct that is represented by a set of logically – and in this case – quantitatively connected variables. Quantitative models include formal analysis (modeling) and applied statistical analysis. Formal analysis (i.e., social choice, linear difference equations, and differential equations) refers to deductive modeling that includes a theorem and proof presentation or computational modeling requiring simulation. Applied statistical analysis involves data analysis (from experimental or secondary sources) using statistical tools.)

The workshop participants acknowledged that a schism had developed between those who engage in formal modeling, focusing on quantifying abstract concepts mathematically, and those employing empirical modeling emphasizing applied statistics. (The participants and their commentaries are listed in Appendix B of the 2002 EITM Report.) As a consequence, a great deal of research in political science is competent in one technical area, but lacking in another. To put it another way, the impaired competency is reflected by either a formal approach with substandard (or no) empirical tests or an empirical approach without formal clarity.

This 'siloed' research – and attendant training regimen – contributes to a failure in identifying the proximate causes explicated in a theory and, in turn, increases the difficulty of achieving a meaningful increase in scientific knowledge. A reason is that researchers limit themselves to the strengths and weaknesses of a single methodological approach. For formal modelers, this manifests itself in not respecting the facts; for researchers who rely exclusively on applied statistics, we find data mining, garbage-can regressions, and statistical patches (i.e., omega matrices) (Granato and Scioli, 2004).

EITM is meant to correct these current methodological practices. When using EITM, scholars are making the ultimate focus of a model, and test is to support a cumulative scientific process, a process geared toward finding a causal mechanism. The ability of a researcher to parse out specific causal linkages among the many factors encountered is fundamental to the scientific enterprise. But, it also should be noted that no one engaged in the scientific enterprise would call finding causal mechanisms – easy. What makes methodological unification so useful in this process is that specifying a model linking both formal and empirical approaches alerts researchers to outcomes when specific conditions are in place. In other words, EITM promotes a dialog between models and tests to not only aid in predictive accuracy but also in understanding the workings of a system (particularly through formalization), which can sometimes occur long before tests and data are available (Powell, 1999; Coase, 1994).

We hasten to add that methodological unification – linking formal and empirical analysis – in the social and behavioral sciences is not new and can be traced primarily to the accomplishments of the Cowles Commission in the 1930s. Created in the 1930s, the Cowles Commission was designed "to foster the development of logical, mathematical, statistical methods of analysis for application in economics and related social sciences" (see http://cowles.econ.yale.edu/about-cf/about.htm). The basis for this linkage is the notion that random samples are governed by a latent and probabilistic law of motion (Haavelmo, 1944; Morgan, 1990). Further, this view argues that formal models, related to an applied statistical model, could be interpreted as creating a sample drawn from the underlying law of motion. A well-grounded test of a theory could be accomplished then by relating a formal model to an applied statistical model and testing the applied statistical model.

Current Methodological Practices: The Shortcomings

The Cowles contributions to the social sciences were far reaching. It was the Cowles Commission that explored the differences between structural- and reduced-form parameters (Morgan, 1990; Heckman, 2000: p. 46). Conditions for identifiability were introduced to aid in this differentiation. The Cowles methodology created new research aimed at determining valid inference through the emphasis of the properties identification and invariance. For *identification*, rules (i.e., rank and order conditions) were devised so that an equation of a model could reveal one and only one set of parameters consistent with both the model and the observations (Koopmans, 1949). A second issue involved the *invariance* of a (structural) relation. If an underlying mechanism is constant in the past and future, then the path of the relevant variable(s) will be predictable from the past, apart from random disturbances (Marschak, 1947, 1953). This work is now part of standard texts in econometrics. We adopt Heckman's (2000: p. 59) terminology below:

> Structural causal effects are defined as the direct effects of the variables in the behavioral equations … When these equations are linear, the coefficients on the causal variables are called structural parameters (emphasis added), and they fully characterize the structural effects.

Heckman also notes there is some disagreement about what constitutes a structural parameter. The disagreement centers on whether one uses a linear model, a nonlinear model or, more, recently a fully parameterized model. In the latter case, structural parameters, can also be called 'deep' to distinguish between "the derivatives of a behavioral relationship used to define causal effects and the parameters that generate the behavioral relationship" (p. 60).

Current methodological practice marginalizes the Cowles Commissions contributions, but also served for the motivation for the EITM initiative and framework. Here we identify two adverse consequences: (1) when used in isolation, formal models miss key empirical findings and can only obscure a more accurate understanding of the inner workings of a system let alone impair predictive accuracy; and (2) empirical modelers' excessive reliance on statistically *significant* results means nothing when the researcher makes little attempt to identify the precise origin of the parameters in question. Absent this identification effort, it is not evident where the model fits facts.

Formal Models and Facts

Formal models can fail to incorporate empirical findings that would assist in providing a more accurate depiction of the relations that are specified. This results in modeling efforts that yield inaccurate predictions or do not fit findings. In fact, data may contradict not just a model's results but also its foundational assumptions. The problem is not just the unreal assumptions, for one way to build helpful models is to begin with stylized assumptions, test the model's predictions, and then modify the assumptions consistent with a progressively more accurate model of reality. Yet, these follow-up steps are too often not taken or left unfinished – with the result being a model that does little to enhance understanding and advance the discipline.

Applied Statistical Procedures that Fail to Identify Mechanisms

Three harmful but common applied statistical practices exist: data mining, garbage cans, and the use of statistical weighting and patching ('omega matrices'). These applied statistical practices lack overall robustness as they obscure fundamental specification error. To see how this occurs, we summarize each practice (Granato and Scioli, 2004):

1. *Data mining*: This practice involves putting data into a statistical package with minimal theory. Regressions (likelihoods) are then estimated until either statistically significant coefficients or coefficients the researcher likes are found. This *stepwise* search is not random and has little relation to identifying causal mechanisms (Lovell, 1983; Denton, 1985).
2. *Garbage cans*: This practice, related to data mining, is where a researcher includes, in a haphazard fashion, a plethora of independent variables into a statistical package and gets 'significant' statistical results somewhere. Researchers who use garbage-can models usually pay little attention to potential confounding factors that could corrupt statistical inferences. Efforts to identify an underlying causal mechanism are also few and far between (Achen, 2005).
3. *Omega matrices*: Data mining and garbage-can approaches virtually are guaranteed to break down statistically. The question is what to do when these failures occur. There are elaborate ways of using (error) weighting techniques *to correct* model misspecifications or to use other statistical patches that influence $s.e.(b)$. In almost any intermediate econometrics textbook one finds a section that has the Greek symbol: Omega (Ω) (Johnston and DiNardo, 1997: p. 189). This symbol is representative of the procedure whereby a researcher weights the data that are arrayed (in matrix form) so that the statistical errors, ultimately the standard error noted above, are altered and the t-statistic is manipulated.

In theory, there is nothing wrong with knowing the Omega matrix for a particular statistical model. The standard error(s) produced by an Omega matrix should only serve as a check on whether inferences have been confounded to such an extent that a Type I or Type II error has been committed. Far too often, however, researchers treat the Omega weights (or alternative statistical patches) as the result of a true model. This attitude hampers scientific progress because it uses a model's mistakes to obscure flaws. An example of this practice is the 'correction' for serial correlation (Mizon, 1995).

We can also evaluate these current practices in relation to how they fail to contribute to a modeling dialog between theory and test (see **Figure 1**). What we see is that the processes of prediction and validation are never directly applied. Instead, the empirical test(s) remains in a loop or dialog with itself. An iterative process of data mining, overparameterization, and the use of statistical patches (Omega matrices) replaces prediction, validation (falsification), and an understanding of the process.

Figure 1 Noncumulative applied statistical practices.

It is important to note when we use the word validation, this is not simply a process of a single theory being tested by the accuracy of its predictions but also in comparison to competing theories on the same phenomena. As Kuhn (1979) states:

> Anomalous observations … cannot tempt [a scientist] to abandon his theory until another one is suggested to replace it…In scientific practice the real confirmation questions always involve the comparison of two theories with each other and with the world, not the comparison of a single theory with the world (p. 211).

The EITM Framework

The EITM framework builds on the Cowles Commission approach. (see Granato (2005) and Granato et al. (2010a,b, 2011) for a description and examples of the EITM framework. An extensive and earlier treatment on the linkage between formal and empirical analysis can be found in Morton (1999).) This framework takes advantage of the mutually reinforcing properties of formal and empirical analysis addressing the challenge(s) above. Why develop a framework? As Ostrom argues the development of a framework is important since "without a framework to organize relevant variables identified in theories and empirical research, isolated knowledge acquired from studies … by … social scientists is not likely to cumulate (Ostrom, 2009: p. 420)."

Mechanism Operationalization

The EITM framework supports on mechanism operationalization. It involves creating measurable devices (what we term analogs) not only on the formal and behavioral side, but also on the empirical side. Behavioral concepts include (but are not limited to) expectations, learning, social interaction, decision-making, strategic interaction, and more. Empirical concepts include (but are not limited to) persistence, measurement error, simultaneity, prediction, nominal choice, and more.

Traditional operationalization involves finding measures for behavioral concepts. These measures are usually a variable of some sort. Mechanism operationalization encompasses this tradition, but also extends it to include the use of operators, frameworks (that can include variables), and tools to represent both behavioral and empirical concepts. EITM places emphasis on finding ways to model human behavior and action and, thereby, aids in creating realistic representations that improve upon simple socioeconomic categorization. Numerous social science disciplines focus a good deal of research effort on the interactions between agent behavior and public policies. The EITM framework make use of structural equation modeling associated with the Cowles Commission, but it also includes alternative probability approaches, computational methods, and experimental methods (Poteete et al., 2010).

From Concepts to Analogs

The EITM framework also uses what we know about theoretical and applied statistical concepts, provides a rigorous basis for these concepts through the use of their respective analogs, and then merges these theoretical analogs with the applied statistical analogs. A *concept* can be thought of as an abstract or general idea inferred or derived from specific instances. An *analog* can be thought of as a device in which a concept is represented by continuously variable – and measurable – quantities. What would develop is a road map for others to modify, correct, or follow. More importantly, one would be providing a transparent linkage between a theory and test. This is not to say the model is correct. Instead, what you would be doing is meeting a minimal requirement that the theory and test are related and, therefore, serve as a basis for evaluating the inner workings of the system, predictive accuracy, or both.

The Three-Step Framework

The EITM framework contains three steps:

Step 1: Identify Focal Concepts

The goal of the EITM framework is a closer integration of theoretical and empirical models. We start, however, not with the development of mathematical structures but with the identification of *concepts*. It is of course standard to suggest that research starts with concepts. We have in mind, however, not the substantive concepts central to political science (such as legitimacy, democratization, attitude formation), but instead to the general attributes of the thing being researched. Consider, for example, the concept of democracy and democratization. Its substantive importance is undisputed, but precisely where one goes from there is unclear. There are simply too many possible ways to proceed.

The goal of this first step in EITM is to transform the focus from the substantive topic to the underlying behavioral process. A student of democracy might focus, for example, on *choice*: how do demographic and attitudinal variables drive individual selection over political parties. Another student might focus on *uncertainty and learning*: given the lack of a 'track record' among political parties in newly democratizing states, how do individuals come to form expectations regarding those parties, and how do those expectations shift in response to political and economic changes? A third student might concentrate on the idea of *bargaining*: how do the various party leaders face the trade-offs between maximizing their potential influence in the political system and maintaining the promise to democratize? The idea is not to ignore the substantive aspects, but to look at substance from a different perspective, one that not only helps clarify the focus of the research, but

also suggests common *behavioral* concerns that make it easier to communicate across subfields and find common elements and approaches. This leads to the second step.

Step 2: Develop Formal and Applied Statistical Analogs

Once the focal concept has been identified, work moves to the second step, the development of formal and applied statistical analogs. Consider, for example, the concept of *persistence*. Theoretically, this conjures up a host of potential analogs: coordination equilibria, Markov chain steady states, locally and globally stable solutions to systems of differential equations, or still lifes in cellular automata models. Similarly, persistence can be tied to a number of statistical models, including autoregressive estimation and asymptotic theory.

Step 3: Unify and Evaluate the Analogs

By starting with the concept and then moving to the theoretical and applied statistical analogs, we guarantee that there must be *something* in common between the theory and the empirical analysis. The idea, then, is to locate the parameters of interest in each that reflect the underlying concept, and then use those to build clearer and stronger links between the mechanisms of the theoretical model and the specification of the statistical methods. The specified linkage not only draws theory and empirics closer, but also provides a way for research to build by showing potential sources of inaccuracies and model failure.

EITM in Practice: Economic Voting

We now demonstrate the EITM framework using published research on economic voting. These studies have refined earlier work and present models of voter sophistication and new applied statistical tests. In the former instance, voters possess the capability to deal with uncertainty in assigning blame or credit to incumbents for good or bad economic conditions. For the latter, applied statistical tests include some of the more advanced tools in time series analysis.

The example we use examines how the behavioral concepts of expectations and uncertainty, when linked to the applied statistical concept of measurement error, create distinct hypotheses in the economic voting literature. The analogs for these concepts are as follows: the formal analog(s) are: conditional expectations modeling, recursive projections, and the law of iterated projections (or expectations). The applied statistical analog is error-in-variables regression.

Step 1: Relating Behavioral and Applied Statistical Concepts: Expectations, Uncertainty, and Measurement Error

Starting with Kramer (1983) and continuing with work that includes (but is not limited to) Alesina and Rosenthal (1995), Suzuki and Chappell (1996), and Lin (1999), there is a substantial quantitative literature on how the economy affects voting behavior. For our purposes we demonstrate how the combined work of Alesina and Rosenthal and Suzuki and Chappell have in their own way contributed constituent parts to the study of economic voting.

The uncertainty that voters face can ideally be tested using the EITM framework. The EITM relation can be found in the following way: when expectations and uncertainty analog(s) are linked to a measurement error analog (error-in-variables regression), it can be shown that parameters in the regression reflect the increasing variance (i.e., uncertainty) of the variables of interest. In other words, as expectations and uncertainty analogs change, the testable economic effect on voting changes as well.

Step 2: Devise Formal and Applied Statistical Analogs

We start with a formal model that uses the behavioral concepts: expectations and uncertainty. Alesina and Rosenthal (1995) provide such a formal model (pp. 191–195). Their model of economic growth is based on an expectations-augmented aggregate supply curve:

$$\widehat{y}_t = \widehat{y}^n + \gamma(\pi_t - \pi_t^e) + \varepsilon_t \qquad [1]$$

where $\widehat{y}_t$ represents the rate of economic growth (GDP growth) in period t, $\widehat{y}^n$ is the natural economic growth rate, π_t is the inflation rate at time t, and π_t^e is the expected inflation rate at time t formed at time $t-1$.

With voter inflation expectations established, we now turn to the concept of uncertainty. Let us assume that voters want to determine whether to attribute credit or blame for economic growth (y_t) outcomes to the incumbent administration. Yet, voters are faced with the uncertainty of determining what part of the economic outcomes is due to incumbent 'competence' (i.e., policy acumen) or simply good luck.

Equation [2], the shock in eqn [1], can be modified to present the analog for uncertainty:

$$\varepsilon_t = \eta_t + \xi_t \qquad [2]$$

The variable ε_t represents the shock that is comprised of the two unobservable characteristics noted above – competence or good luck. (This following modification is commonly referred to as a 'signal extraction' or measurement error problem.) The first, represented by η_t, reflects 'competence' that can be attributed to the incumbent administration. The second, symbolized as ξ_t, are shocks to growth that are beyond administration control (and competence). Both η_t and ξ_t have zero mean with variance(s) σ_η^2 and σ_ξ^2, respectively.

Note also that competence can persist and *support* reelection. This feature can be characterized as an MA(1) process:

$$\eta_t = \mu_t + \rho\mu_{t-1}, \quad \rho \in (0, 1] \qquad [3]$$

where μ_t is $iid(0, \sigma_\mu^2)$. The parameter ρ represents the strength of the persistence. The lag or lags allow for retrospective voter judgments.

If we reference eqn [1] again, let us assume that voters' judgments include a general sense of the average rate of growth ($\widehat{y}^n$) and the ability to observe actual growth ($\widehat{y}_t$). Voters can evaluate their difference ($\widehat{y}_t - \widehat{y}^n$). Eqn [1] also implies that when voters predict inflation with no systematic error (i.e., $\pi_t^e = \pi_t$), the result is noninflationary growth that does not adversely affect real wages.

Next, we tie economic growth performance to voter uncertainty. We formalize how economic growth rate deviations from the average can be attributed to administration competence or fortuitous events:

$$\widehat{y}_t - \widehat{y}^n = \varepsilon_t = \eta_t + \xi_t \qquad [4]$$

Equation [4] shows that when the actual economic growth rate is greater than its average or 'natural rate' (i.e., $\widehat{\gamma}_t > \widehat{\gamma}^n$), then $\varepsilon_t = \eta_t + \xi_t > 0$. Again, the voters are faced with uncertainty in distinguishing the incumbent's competence (η_t) from the stochastic economic shock (ξ_t). However, because competence can persist, voters use this property to make forecasts and give greater or less weight to competence over time.

To demonstrate this behavioral effect, substitute eqn [3] in [4]:

$$\mu_t + \xi_t = \widehat{\gamma}_t - \widehat{\gamma}^n - \rho\mu_{t-1} \qquad [5]$$

We now determine the optimal estimate of competence, (η_{t+1}), when the voters only see $\widehat{\gamma}_t$. We demonstrate this result by making a one-period forecast of eqn [3] and then solve for its expected value (conditional expectation) at time t:

$$E_t(\eta_{t+1}) = E_t(\mu_{t+1}) + \rho E(\mu_t|\widehat{\gamma}_t) = \rho E(\mu_t|\widehat{\gamma}_t) \qquad [6]$$

where $E_t(\mu_{t+1}) = 0$. Using this analog for expectations in eqn [6], we see that competence, η_{t+1}, can be forecasted by predicting μ_{t+1} and μ_t. Since there is no information available for forecasting μ_{t+1}, voters can only forecast μ_t based on observable $\widehat{\gamma}_t$ (at time t) from eqn [5].

Step 3: Link the Formal and Applied Statistical Analogs

Now, using the method of recursive projection and eqn [5] the behavioral analog for expectations is linked to the empirical analog for measurement error (an error-in-variables 'equation'):

$$E_t(\eta_{t+1}) = \rho E(\mu_t|\widehat{\gamma}_t) = \rho\frac{\sigma_\mu^2}{\sigma_\mu^2 + \sigma_\xi^2}(\widehat{\gamma}_t - \widehat{\gamma}^n - \rho\mu_{t-1}) \qquad [7]$$

where $0 < \rho\frac{\sigma_\mu^2}{\sigma_\mu^2+\sigma_\xi^2} < 1$. Equation [7] shows that voters can forecast competence using the value of $\widehat{\gamma}_t - \widehat{\gamma}^n$, but also the 'weighted' lag of μ_t (i.e., $\rho\mu_{t-1}$).

In eqn [7], the expected value of competence is *positively* correlated with economic growth rate deviations. Voter assessment is filtered by the coefficient, $\frac{\sigma_\mu^2}{\sigma_\mu^2+\sigma_\xi^2}$, which represents a proportion of competence that voters are able to interpret and observe. The behavioral implications are straightforward. If voters interpret that the variability of economic shocks come solely from the incumbent's competence (i.e., $\sigma_\xi^2 \to 0$), then $\frac{\sigma_\mu^2}{\sigma_\mu^2+\sigma_\xi^2} \to 1$. On the other hand, the increase in the variability of uncontrolled shocks, σ_ξ^2, confounds the observability of incumbent competence since the signal coefficient $\frac{\sigma_\mu^2}{\sigma_\mu^2+\sigma_\xi^2}$ decreases. Voters assign less weight to economic performance in assessing the incumbent's competence.

To sum up, Alesina and Rosenthal provide an EITM connection between eqns [1], [3] and their empirical tests. *They link the behavioral concepts – expectations and uncertainty – with their respective analogs (conditional expectations and measurement error) and devise a signal extraction problem*. While the empirical model resembles an error-in-variables specification, testable by dynamic methods such as rolling regression (Lin, 1999), instead they estimate the variance-covariance structure of the residuals.

Summary and Discussion

We have described the weaknesses of current research practices and how they do not contribute to a valid modeling dialog. The failure to tie theories to tests and provide meaningful feedback means scientific accumulation suffers. The EITM framework is a response to this methodological status quo in formal and empirical analysis.

It should also be noted that implementation of the EITM framework *requires* some changes in graduate training. If methodological instruction continues on its current path, then successive generations will only repeat the shortcomings noted.

As a final thought, and if we were to sum up the EITM framework, we would argue it is a guide to unification. But, there is no set formula for what tools to use. What dictates the tools to use is how you characterize your idea. At that point, you will need to look in a tool box and use the specific formal and empirical techniques available and appropriate. Competing characterizations are appropriate and should be evaluated on their ability to represent accurately the workings of the system as well as their predictive power.

Appendix: Notes on Analogs

Expectations and Uncertainty: The Tools and Components that Build the Behavioral Analog

The tools that allow us to link an error-in-variables regression with eqn [7] are more complicated than in the first example. The discussion below is based in part on Sargent (1987: pp. 223–238). The behavioral (formal) analogs for expectations and uncertainty center on *rational (conditional) expectations* modeling. The rational expectations hypothesis can be characterized as individuals forming their subjective expectations of a variable (y^e) consistent with an objective mathematical expectation of (y) that is conditional on all available information (Ω). (Note: this symbol should not be confused with the omega matrix discussion in Section Applied Statistical Procedures that Fail to Identify Mechanisms.)

Formally, rational expectations can be defined as a mathematical expectation (projection) of the probability distribution of y given a set of information, $\Omega = \{x_0, x_1, \ldots, x_n\}$:

$$y^e = P(y|\Omega) \qquad [1a]$$

Assuming that the mathematical expectations are formed in a linear expression:

$$P(y|\Omega) = a_0 + a_1x_1 + a_2x_2 + \cdots + a_nx_n = \sum_{i=0}^{n} a_ix_i \qquad [1b]$$

where $x_0 = 1$. Given the orthogonality principle where $E[(y - P(y|\Omega))x_i] = 0$ for all i, we have the following normal equations

$$\begin{bmatrix} Ey \\ Eyx_1 \\ Eyx_2 \\ \vdots \\ Eyx_n \end{bmatrix} = \begin{bmatrix} 1 & Ex_1 & Ex_2 & \cdots & Ex_n \\ Ex_1 & Ex_1^2 & Ex_1x_2 & \cdots & \\ Ex_2 & Ex_1x_2 & \ddots & & \\ \vdots & \vdots & & \ddots & \\ Ex_n & & & & Ex_n^2 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix} \qquad [1c]$$

Based on the orthogonality principle, a′ can be uniquely determined (see Sargent, 1987: pp. 223–226). From [1c], we can calculate the vector of a's:

$$\begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix} = \left[Ex_ix_j\right]^{-1}\left[Eyx_k\right] \qquad [3d]$$

Now apply the formulation above to the following linear expression and apply the least squares rule for $n = 1$:

$$P(y|1, x_1) = a_0 + a_1x_1$$

For eqn [1c], we have:

$$\begin{bmatrix} Ey \\ Eyx_1 \end{bmatrix} = \begin{bmatrix} 1 & Ex_1 \\ Ex_1 & Ex_1^2 \end{bmatrix}\begin{bmatrix} a_0 \\ a_1 \end{bmatrix}$$

where in normal equation form, the result is:

$$a_0 = Ey - a_1Ex_1$$

and then applying the least squares rule:

$$a_1 = \frac{E(y - E(y))(x_1 - Ex_1)}{E(x_1 - Ex_1)^2} = \frac{\sigma_{x_1y}}{\sigma_{x_1}^2}$$

where σ_{x_1y} is the covariance between x_1 and y, and $\sigma_{x_1}^2$ is the variance of x_1.

Relating the Behavioral Analogs to the Empirical Analog for Measurement Error: Error-in-Variables Regression

The linkage between conditional expectations with the law of iterated expectations has a natural relation with error-in-variables regression (measurement error). There are many examples of this 'EITM-like' linkage and they generally fall under the umbrella of *signal extraction* problems. This economic voting example is a signal extraction problem where there is uncertainty over attributing growth performance to incumbent competence or good luck.

Signal extraction problems can be expressed in the following way. Suppose an agent wants to estimate a random variable 's' but only 'sees' the variable x:

$$x = s + n$$

where $Esn = 0$, Es^2, $En^2 < \infty$, $Es = En = 0$.

Therefore using a projection operator and applying the least squares rule we have:

$$P(s|1, x) = a_0 + a_1x$$

and

$$a_1 = \frac{E(xs)}{Ex^2} = \frac{E[(s+n)s]}{E(s+n)^2} = \frac{Es^2}{Es^2 + En^2}$$

but

$$a_0 = 0$$

The result is that there can be a behavioral basis for an error-in-variables regression (see Johnston and DiNardo (1997: pp. 153–155)). The identity below is in the same form as eqn [7]:

$$P(s|1, x) = \frac{Es^2}{Es^2 + En^2}x = \frac{\sigma_s^2}{\sigma_s^2 + \sigma_n^2}x$$

Abstract

This article reviews the history and development of polling that has been relevant to political science in the United States. It covers the early 'straw polls' to the advent of 'scientific polling' based on statistical sampling, to telephone surveys, exit polls, and later technological developments and ensuing debates. It describes the general use of survey research to study public opinion and political behavior; the sources of errors in surveys and other methodological issues; and the topics in political science regarding public opinion and democracy that polling has helped examine.

Introduction

Opinion *polls* or *surveys* are widely used in political science and other fields to study the behavior of individuals and publics in the *aggregate* – including voters and smaller population subgroups. Academicians and practitioners engaged in opinion polling have preferred to call themselves 'survey researchers,' in contrast to 'pollsters' who carry out nonacademic polls to predict election results and report in the news media the mass public's or others' opinions and attitudes; or who work as consultants doing proprietary research (including market and public relations analysis) for political parties, political candidates (including leaders in office), or other clients (Converse, 1987; Moore, 1992; Jacobs and Shapiro, 1995; Eisinger, 2003). Polls and surveys are synonymous, but their quality – validity and reliability – can vary widely. Researchers select and ask questions concerning attitudes, behavior, personal characteristics, and other information that survey respondents can provide. These responses are counted, analyzed statistically, and interpreted depending on the types of questions asked and research topics examined. This article reviews the history and development of polling that has been relevant to political science in the United States from the early 'straw polls' to the advent of 'scientific polling' using statistical sampling, to telephone surveys, exit polls, and later technological developments and ensuing debates (on polling's broader relevance in comparative perspective, see e.g., Dalton and Klingemann, 2007; Frankovic et al., 2009). It focuses on the general use of survey research to study public attitudes, opinions, and political behavior; the sources of errors in surveys and other methodological issues; and the topics in political science regarding public opinion and democracy that polling has helped examine.

Straw Polls

Polling had expanded greatly worldwide by the late-twentieth century. Its origin occurred in the United States beginning with election 'straw polls' in the nineteenth century. These were motivated by people's curiosity about public opinion and voting in upcoming elections, and there was a market in the mass media for this kind of information. Opinion surveys have been a major part of the rise of quantification in society consistent with Max Weber's writing about the role of calculation and rationality in social life (Herbst, 1993). The earliest straw poll counterparts of modern opinion surveys occurred in the 1824 presidential election and were reported in the partisan press; the use of different types of these in politics and journalism increased until the emergence of more 'scientific' polling in the 1930s (Smith, 1990). These straw polls used 'convenience samples' in public gatherings and setting and took many different forms, including oral counts, hand raising, paper ballots, and preferences recorded in 'poll books.' The participants were *self-selected* in ways that were likely to produce *selection bias*, in which the results of these polls would be influenced by the characteristics of those who were able to participate and who might be different from the electorate or population to which the poll results would be generalized. Reporters and partisans, nonetheless, treated these polls as indications of candidates' election chances, and the track record of large-scale straw polls was good: the 1896 *Chicago Record*'s postcard ballots returned by over 200 000 registered voters from Chicago and eight surrounding states found that Republican presidential candidate William McKinley far ahead of Democrat William Jennings Bryan; and in Chicago it got within 0.04% of the actual vote. More (in)famously, *The Literary Digest*'s ballot cards sent to millions of its subscribers and individuals from telephone, car registration, and voter lists provided accurate estimates of presidential election winners from 1916 to 1932 (see Frankovic et al., 2009).

'Scientific' Polling

The problems associated with the representativeness and precision of such polls became clear publicly when the accuracy of the *Literary Digest* poll was called into question by George Gallup and other new 'public pollsters,' statisticians, and social scientists. Gallup became the most widely known, if not the most important figure, in what became modern-day survey research (along with Elmo Roper and Archibald Crossley; with Paul F. Lazarsfeld, Hadley Cantril, and others emerging in the academic world). He was a vocal proponent of polling to facilitate democratic responsiveness (Gallup and Rae, 1940), while ultimately using his public polls to promote his renowned proprietary survey research company. Although Gallup's first national election poll in 1936, done through

geographic and quota sampling and in-person interviews, actually underestimated the margin of Democrat Franklin Roosevelt's election victory over Republican Alfred Landon, what is remembered is that it visibly triumphed over the *Literary Digest* in predicting the winner.

The Gallup poll represented the electorate far better than did the *Digest*, confirming the superiority of more 'scientific-' minded survey methods. In principle, these methods allowed each potentially eligible adult voter (or eligible respondent, given the research objectives of a particular poll) much closer to an equal probability of selection, compared to the *Digest* that introduced an upper status selection bias from the initial lists it used. In addition, there was a further bias in the same direction as a consequence of those who chose to return the ballots (Squire, 1988). The New Deal partisan realignment that occurred by 1936 was a class-based transformation of the electorate, so that the underrepresentation of economically downscale and increasingly democratic voters was much more consequential for the *Digest* – and dramatically so – than in previous elections.

These early polls involved sending interviewers to many locations around the country and then allowed interviewers to select their respondents to fill 'quotas' based on the population characteristics to be represented in the poll. This also led to an upper status bias, though less severe than in the *Digest* poll. This explains why Gallup got the winner correct, but was numerically off in predicting Roosevelt's victory *margins* in the 1940 and 1944 elections. These and other problems in the early polls, which included ceasing their interviews weeks before an election, were debated widely among pollsters and social scientists after the polling debacle in the 1848 presidential election, when the polls predicted incorrectly that Republican Thomas Dewey would defeat Democratic President Harry Truman (Mosteller et al., 1949). Gallup and other pollsters subsequently improved their sampling methods. Also beginning to conduct large-scale opinion and voting studies at this time, survey professionals and academic researchers engaged in a concerted effort to improve and defend opinion polling and to measure and examine closely public opinion and mass political behavior (see, e.g., Sheatsley and Mitofsky, 1992; Mitofsky, 1998; on election polling and its future, see Hillygus, 2011).

Emerging Uses of Public Opinion Research

Public opinion analysis advanced professionally in the United States with the establishment of the journal, *Public Opinion Quarterly*, in 1937 and the American Association for Public Opinion Research in 1947, followed later by other associations of American and international polling organizations and researchers (see Frankovic et al., 2009). While Gallup emphasized that polling could and should make the impact of public opinion felt more broadly in government and society (Gallup and Rae, 1940; cf Herbst, 1993), the journal was founded on the premise that mass opinion had already shown its importance and what was needed was research concerned with influences on public opinion – whether through constructive education and leadership, or less benign manipulation and propaganda (see the emphasis on leadership in Key, 1961) – and methodologies for studying these opinions, including especially polling.

University-based survey research had its beginnings in 1939–40 with sociologist Paul Lazarsfeld's Office of Radio Research, later renamed the Bureau of Applied Social Research at Columbia University. This history is described by Rossi (1959), Natchez (1985), and especially Converse (1987). Lazarsfeld and his colleagues in *The People's Choice* (Lazarsfeld et al., 1944) did the first sophisticated survey study of presidential elections in 1940 in Erie County, Ohio. This was followed by *Voting* (Berelson et al., 1954), a study of the 1948 election in Elmira, New York. These early studies were highly sensitive to methodological issues in survey research and contributed to the development and use of panel surveys (the interviewing of the same respondents over two or more points in time) and complex research designs. Two of the largest and most widely known research centers that developed the capacity to do long-term national surveys are the National Opinion Research Center (NORC), which was established in 1941 at the University of Denver and moved to the University of Chicago in 1947; and the University of Michigan's Survey Research Center (SRC, at the Institute for Social Research (ISR)), established in 1946. With the publication of *The Voter Decides* (Campbell et al., 1954), the funding and locus for national election surveys shifted to Michigan's SRC, which led to the publication of *The American Voter* (Campbell et al., 1960) and the continuing series of American National Election Studies and studies based upon them (Nie et al., 1976/1979; Miller and Shanks, 1996; Lewis-Beck et al., 2008; Bafumi and Shapiro, 2009; Abramson et al., 2012).

The years from Roosevelt's election through World War II were important for professionalized polling. Roosevelt and the Democratic Party had the first recognizable political pollster/consultant Emil Hurja in their 1932, 1934, and 1936 election victories (Holli, 2002). Government commissioned survey research played a significant role in national leaders' and administrators' dealing with issues related to the World War II mobilization efforts and the economy at home; this included monitoring reactions to prices, rationing, and war bond drives, and examining labor and other war-relevant policy areas (see Sparrow, 2011). A major large-scale survey study of the military was conducted by Samuel Stouffer et al. in *The American Soldier* (1965[1949]), which examined army life, morale, and ultimately issues related to demobilization at end of the war. Government surveyors became leaders in academic survey research after the war, such as at Michigan's ISR/SRC.

During the war Roosevelt had the first 'presidential pollster,' Hadley Cantril, whose Office of Public Opinion Research provided information about public opinion related to the conducting of the war, as Roosevelt and his advisors felt the constraints of public opinion and attempted to anticipate, lead, and – arguably – manipulate it. This began with Roosevelt easing the United States into aiding the British against Nazi Germany prior to the United States entering the war after the Japanese attack on Pearl Harbor; then his administration's efforts to gain support for giving priority to the war in Europe versus the war against Japan; through the final decision to so require unconditional surrender from both the Germans and the Japanese (see Casey, 2001). Into the postwar years and the Cold War, the State Department commissioned NORC to

conduct what were 'secret' foreign policy surveys. Upon learning of these surveys, Congress cut off funding for them, arguing that members of Congress were the representatives of public opinion and that separate government polling had no place in representing the people (Eisinger, 2003). This did not, however, preclude the State Department's United States Information Agency from conducting surveys abroad to inform American foreign policy-making.

Subsequent Expansion

Professional polling and academic survey research expanded after 1950 (see Frankovic et al., 2009). The polling landscape included additional public pollsters of note who provided their survey results to the mass media and other subscribers along with some free public releases of poll results (e.g., Louis Harris, Daniel Yankelovich, and later the Pew Research Center, among others). Polling experienced its greatest expansion beginning in the 1970s and especially the 1980s, when it was found that sufficiently representative and accurate polls could be done less expensively by telephone than in person (based on experiments comparing polls conducted by phone with those done face-to-face), eventually leading most pollsters to do their surveys by phone, as the penetration of phones nationwide reached the 95% level. *Random Digit Dialing* (RDD and variants of it) provided more direct probability samples of households with phones, and the advent of *Computer-Assisted Telephone Interviewing* (CATI) expedited telephone surveying and data processing. The national news media, which had relied on polling by public pollsters, began sponsoring and conducting their own polls, establishing their own, often joint telephone polling operations (e.g., CBS News/*New York Times*, and ABC News/*Washington Post* polls) or making arrangements to contract-out polls in which they controlled the content and reporting of results (see Gollin, 1980; Mann and Orren, 1992). Moreover, in this way the media had *independent* sources of data from the polling results that self-serving political parties, candidates, and interest groups might send their way or publicize. The media polls greatly expanded the polling data that political scientists and other researchers could draw on.

Nonpolitical government survey research continued for public administration and policy-related purposes, including U.S.-Census-related surveys and survey data collection bearing on public health and the nation's general welfare (Converse, 1987; see Frankovic et al., 2009). The political side of polling has been dominated by market researchers and others who expanded their enterprises into consulting for political parties and candidates (e.g., see Moore, 1992). Presidential polling has been paid for by the political parties or by campaigns, not through government funding. After Cantril's polling for the Roosevelt administration, the history of presidential pollsters picks up with Louis Harris working for candidate and later President, John F. Kennedy, as polling and political consultants became a staple of political campaigns and as leaders brought them along informally and later more formally as they entered office. Kennedy was followed by Presidents Lyndon Johnson and Richard Nixon, with pollsters Oliver Quayle, David Derge, the Opinion Research Corporation, and Robert Teeter (Market Opinion Research); President Jimmie Carter and pollster Patrick Caddell; President Ronald Reagan and pollster Richard Wirthlin; President George H.W. Bush and Robert Teeter; President Bill Clinton and Stanley Greenberg, followed later by Dick Morris, Mark Penn, and Douglas Schoen; and Presidents George W. Bush and Barack Obama with various pollsters/consultants. Most notably, again, this polling was not used to respond to mass opinion as Gallup had posited, but rather to help presidential administrations and other leaders determine how to move the public, especially voters, in the direction of their preferred policies or ideological goals (see Jacobs and Shapiro, 1995, 2000).

Academic survey research flourished as well. In addition to the American National Election Studies that started in 1948, the NORC General Social Surveys conducted since 1972 have been widely used by social scientists including political scientists. A number of state universities established survey research centers, which could be used to poll the nation, states, and localities. Later, private colleges and universities began doing polls for purposes of promoting their schools' visibility for fundraising and other purposes, some of which expanded to include media partnerships in doing especially state- and local-level polling. Perhaps most important, archives were established to assemble and make available polling results and data sets for academic and other research, including especially the surveys done by the public polling and media organizations. The leading archives in the United States include the Roper Center for Public Opinion Research (University of Connecticut), the Inter-university Consortium for Political and Social Research (University of Michigan), and the Odum Institute (University of North Carolina). These archives are crucial to historical research on public opinion in the United States, including studies of long-term opinion trends – and their causes and consequences – which utilize the available polling data since the 1930s (Page and Shapiro, 1992; Mayer, 1993; on the study of public opinion and 'American Political Development,' see Shapiro, 2014).

Methodological and Technical Issues

While polling conducted by these different organizations depends on an understanding and use of scientific sampling to draw inferences about a target population (e.g., national or local, the entire adult population or particular subpopulations, 'likely voters,' or elites), polls can be conducted in different ways depending on the research goal, the kind of survey questionnaire to be administered, and the available resources (i.e., money and time). In-person national polling – typically done by first randomly sampling geographic locations, then households in these locations, and then random sampling within households – is the most expensive and time-consuming survey mode because of travel and other costs. Face-to-face interviews can involve longer surveys, the use of visual aids, and 'secret ballots' (or turning over the interviewer's portable computer to respondents in Computer-Assisted Personal Interviews) for responses to sensitive questions.

In-person election 'exit polls' (usually with paper questionnaires that respondents can fill out) that are used as a factor in projecting election results and that, more importantly,

provide the basis for more in-depth statistical analysis of voting behavior, are short and efficient surveys, based on random samples of voters exiting election sites. Exit polling has been controversial in the United States due to the 'early' reporting of results that might affect the behavior of those who vote later in the day. Moreover, the data have to be statistically weighted for the actual vote results due to selection biases that have come to overrepresent Democratic Party voters. These and other complications contributed to controversies regarding the 2000 and 2004 presidential elections (see Frankovic et al., 2009).

Besides the advantages already noted, telephone polling is easier to monitor and validate than in-person interviews; however, it excludes households without telephones, and it has higher rates of nonresponse due to households that are not reached (no answers, busy signals, answering machines, and refusals to participate); it is also easier in person to make contact with respondents and establish rapport. Mail surveys are the least expensive but produce low response rates unless extensive follow-ups are made (Dillman et al., 2009). Low response rates and the increasing potential for selection or nonresponse bias have emerged as the most pressing methodological problems currently facing survey researchers, initially as the result of the proliferation of telephone surveys, telemarketing, and solicitations that interrupt and impose upon people's time. This problem has been compounded dramatically by the proliferation of the use of cell phones, which are more complicated to call in the United States where federal law prohibits the use of the automated dialers typically used in CATI systems (e.g., see Groves and Couper, 1998; Groves et al., 2009; Frankovic et al., 2009; Brick, 2011; Couper, 2011; Baker et al., 2013). Sampling cell phones, however, has the advantage of directly sampling individuals, but how readily individuals can – and will – participate in cell phones surveys adds another layer of cost and complexity. At this writing, more than 50% of the adult population is 'mostly' or only reachable by cell phone (Blumberg and Luke, 2013), so that telephone surveys must include cell phones.

These developments and added costs have led to efforts to employ new technology, which has contributed to the expansion in new directions of polling in the United States. This has included interactive voice response polls ('Robo-Polls') that are fully automated surveys with a recorded interviewer asking questions and respondents entering answers by touching numeric phone keys. These polls save interviewer costs and standardize the verbalizing of the questions (avoiding 'interviewer effects'), but they provide no control over respondent selection, do not include cell phones unless they include a manual element, and have lower response rates.

Further, to deal with costs as well as with the difficulty in reaching individuals by phone, and to expedite the polling process, online/Internet surveying has had substantial appeal. It provides greater ease with which respondents can complete self-administered surveys at their convenience, without the disruption of a phone call (and without interviewer effects). Researchers can administer complex questionnaires, include visual aids and graphic or multimedia presentations, and thereby, if desired, conduct greatly enhanced experiments with random assignment of 'treatments' than might be conducted through CATI or other means. While the penetration of online access has expanded enormously, Internet surveys present serious methodological challenges related to the ability to sample fully from the population they want to cover and thereby offer valid statistical conclusions. Since there is no available listing of all electronic e-mail addresses, or a method akin to RDD, it is impossible to directly draw a probability sample. One approach in the United States has been to use RDD, address-based sampling, or in-person survey probability sampling methods to draw random samples of adults, and then giving online access to respondents without such access in establishing 'Internet panels' of individuals who are available to participate subsequently in several surveys; there are then cost savings in not having to draw and survey multiple new samples from the population at large. A less expensive and increasingly used, but somewhat more controversial, method involves recruiting thousands of volunteers to join online panels recruited through invitations on Internet sites, and to adjust for any selection bias through sophisticated methods of 'propensity score' weighting or 'matching' as fully as possible to the demographic composition of the population. It is also possible to do surveys using mixed or multiple modes, but these have not been used extensively in public opinion and election surveys (see Frankovic et al., 2009; Dillman et al., 2009; Baker et al., 2013).

Other Sources of Error

Beyond the above issues of population coverage and nonresponse bias that can lead to the need, at minimum, to apply weights to the data, there are other sources of error in polling. Statistical 'sampling error' is the most widely cited and it refers to error in survey results that is a consequence of having data for a *sample* of a certain size and not for the entire population being sampled. There are, however, other important and less directly quantifiable sources of error. These include the potentially substantial effects of the *mode* of surveying used (in person, phone, mail/paper, online); question wording and question order or context effects (including the order in which response categories are ordered); coding and data processing errors; problems in imputing missing data; and the effects that interviewers – including their ascriptive characteristics such as race, gender, and age – can have on responses to questions. Particularly important, there may be *conceptualization* and *specification* problems that bear on the ultimate validity of opinion measures. For example, in some cases, researchers assume that respondents have genuine attitudes and opinions, or particular issues are highly salient, when they may not be, so that responses to questions may be transitory survey responses or 'nonattitudes.' Care needs to be exercised in drawing inferences about actual behavior from survey measures of opinion, and self-reports of future – or even past – behavior. *Reported* voting in a postelection survey may not match actual behavior confirmed by information on 'validated' votes. Last, errors can occur in how survey results are *reported* or *interpreted*. While issues of reporting and interpretation can be contentious, efforts to address this have involved making information on survey data more

widely available and transparent, especially through free online sources including '*aggregators*' of survey data (e.g., *pollster.com*, *realclearpolitics.com*, *fivethirtyeight.com*, *pollingreport.com*) and the 'transparency initiative' of the American Association of Public Opinion Research (e.g., see Schuman and Presser, 1981; Cantril, 1991; Mann and Orren, 1992; Traugott and Lavrakas, 2007; Frankovic et al., 2009; Dillman et al., 2009; Asher, 2012; Schaeffer and Dykema, 2011; Newport et al., 2013).

Contributions to Political Science: Public Opinion and Democracy

With technological and methodological issues under control, polling gave political scientists in the United States the opportunity to study empirically the nature and role of public opinion in American democracy, as well as to engage in basic social scientific research on the political psychology and behavior of individuals and of the public as a collective.

One initial debate as professional and academic polling began and that still continues concerns the conceptualization of 'public opinion' as an aggregation of individuals' equal opinions that can simply be counted up in polls. That is, polling led to *authoritative* statements about public opinion based on *data*. While from a populist standpoint, counting everyone equally in this way could be justified normatively, for critics of polling the crystallizing and channeling of public opinion into politics involved broader processes that included social forces, organized groups, political parties, and the role and context of institutions, which polls could not capture (see Blumer, 1948; Rogers, 1949). Some also argued that the existence of polling gives the public a false sense that its voice is sufficiently represented in the political process (Herbst, 1993).

Second, the findings of the early Columbia and Michigan academic studies of public opinion and voting fueled criticisms regarding the normative role of public opinion in a democracy. The early survey results raised questions about whether citizens exhibited the desired 'democratic competence' to warrant political leaders and government to be responsive to them. The public did not appear to fit the civics book expectations of knowledgeable and attentive citizens who held well reasoned and stable opinions, and who voted based on issues not on less substantive concern. Rather, individuals fell short in these respects but were influenced by affective partisan loyalties and other nonsubstantive concerns in their personal socioeconomic environments. This is still widely debated and a different picture of public opinion emerges in looking at the opinions and behavior of the public in the *aggregate* over time, not as separate individuals, and in changing social, economic, political, and informational contexts or environments. Patterns of statistical relationships found in public opinion data, and change and stability in public preferences over time, occur for identifiable reasons and are 'rational' in that sense. This does not mean that public is necessarily wise: the extent to which it depends on the information made available to it by the nation's leaders and others who offer guidance through the mass media – including what the media provide through independent analysis and commentary (see Key, 1961; Sniderman et al., 1991; Page and Shapiro, 1992; Glynn et al., 2004; Gilens, 2012; cf Converse, 1964; Zaller, 1992). The increasing partisan polarization and conflict in the United States that has occurred at the elite level since the 1970s, if not earlier, penetrated to the level of mass opinion, in a way that has produced partisan attachments among the public that are much more issue and ideologically based than these loyalties were found to be in the early voting studies, indicating that those findings that reflected badly on the American public were time bound. But it is uncertain what long-term consequences this change in the nature of public opinion will have for American politics (see Bafumi and Shapiro, 2009; Shapiro and Bloch-Elkon, 2008; Shapiro and Jacobs, 2011).

Polling has enabled political scientists to examine a normative and empirical question central to theories of democracy: what is the role of democratically elected governments and leaders with respect to public opinion? Should they respond to or lead the public? Have government leaders and policies been responsive to public opinion? The normative debate is an ongoing one (e.g., see Newport et al., 2013). Empirically, as noted earlier, polling has not been used explicitly by leaders and policy-makers to respond to public opinion. Nonetheless, there is substantial evidence that public opinion matters in ways consistent with the expected role of electoral incentives and accountability. Shapiro (2011; Newport et al., 2013) provides a review of the now-enormous body of empirical research, which ranges from studies of constituency representation, state-level politics, and policy-making; studies of consistency or 'congruence' between national policies and majority public opinion, to time series studies of trends in public preferences, ideology, and government policies. The overall finding from this work is a highly robust but far from complete connection between public opinion and policy-making. The relationship is stronger for highly salient issues and, under other conditions, consistent with electorally accountable leaders responding to the opinions of voters (see Erikson et al., 2002; Shapiro, 2011).

These robust correlations over extended time periods between public opinion and policies do not preclude the possibility that government may be more responsive to some segments of the public than others; that is, to those who are more affluent and thus revealing political inequality due to economic inequality. Survey research has long revealed in the political science research on political participation that there is a socioeconomic bias in participation (for a review, see Schlozman et al., 2012), and recent research has looked more closely at the policy consequences of this. Some research has found that the policy preferences of the affluent were better represented by U.S. senators than those of lower income groups, and that beyond legislative voting, national policies were more likely to be enacted when supported by larger percentages of the affluent as opposed to support from those with middle and lower incomes (Bartels, 2008; Gilens, 2012).

In addition to these debates about such important questions about democracy in the United States and elsewhere, survey research has also contributed to advances in basic social science research in the areas of political psychology and political communication, which have been concerned with the broad range of possible influences on public opinion and voting. Much important research has come from the use of

experimental methods in laboratory settings and in both telephone and Internet survey experiments with national cross-sectional samples of adults (see Mutz, 2011; Vavreck and Iyengar, 2011). The innovative 'deliberative polls' developed and conducted by Fishkin (2009) have included large-scale experiments to evaluate the effects of both information and group discussions/deliberations on the opinions of representative national survey samples of the American public that have been brought together in one location to learn about and debate important policy issues.

The range of media (including *agenda-setting*, *framing*, and *priming* effects) and other influences on public opinion that have been studied is enormous as well as are the types of opinions examined (see the chapters in Shapiro and Jacobs, 2011). These include both *cognitive* and *affective* psychological influences, including the role of personality (e.g., Marcus et al., 2000; Mondak, 2010; Lodge and Taber, 2013); the social and biological bases of public opinion, including gender; the role of values, ideology, and partisanship; racial and ethnic differences in public opinion and political behavior; the role of religion, class, and knowledge and sophistication; and age and socialization processes. These influences play out across voter choices and public opinion toward different domestic and foreign policy issues – from economic welfare and 'big government issues,' including regulation; to the history of civil rights, civil liberties, and criminal justice in the United States; to other present day issues including abortion, gay rights, immigration, environmental protection, energy policy, and gun control; and foreign policy toward all regions of the world, war, national security, and terrorism (e.g., see Page and Shapiro, 1992; Shapiro and Jacobs, 2011; Erikson and Tedin, 2011).

Abstract

Political science as a discipline began to develop at American universities in the late nineteenth century. A new departmental structure of American universities, a birth of the disciplinary association and the founding of specialized publications created an academic community with transferable merits. After the war, the American model started to influence the study of politics worldwide, beginning in Western Europe. Today, the discipline is rapidly advancing especially in Asia and in Latin America. The past 60 years have witnessed political science becoming a pluralist discipline with different research traditions.

Study of Politics vs Political Science as a Discipline

Politics has been discussed, evaluated and studied since the ancient times. It has also been taught at universities for centuries. However, the academic discipline of political science dates only from the late nineteenth century. This contradiction is due to the nature of academic disciplines. Although universities have existed at least since the founding of the University of Bologna in 1088, the medieval universities did not have much in common with modern universities starting to develop in the nineteenth century. New European higher education ideologies (Humboldt in Germany, Newman in Britain, the Napoleonic reforms in France) changed universities thoroughly. At the same time, American universities adopted and transformed European ideologies into a new mold. An important American innovation was the departmental structure of universities, which was created between 1890 and 1910. At that time, it was an internationally unique system. Departments stood between individual professors and the university as a corporate body. They allowed the better recognition of disciplines and formed a group of scholars with transferable merits (Abbott, 2001: pp. 122–123).

In spite of the long heritage of political thinking in Europe, from the Sophists to Hegel and Marx, the modern political science was born in the United States. The main reason for this is the organizational and institutional change of American universities. On the other hand, university departments are not enough for a subject of teaching to be a discipline. A discipline needs a community of scholars interacting and communicating with each other across institutions. It also needs publishing outlets, journals, and disciplinary series. Also in this respect, American political scientists created conditions for the separate political science discipline in the late nineteenth/early twentieth century.

Scientific disciplines also need a favorable social environment to develop. For political science, free interaction and communication between scholars are basic conditions for research. That is why political science, more than many other disciplines, has been tied to the development of democracy (Easton et al., 1995). Without the freedom of association and speech, the study of politics has been one sided, narrow, and ideological. For this reason, authoritarian tendencies have often limited the study of politics in many countries. The United States as 'the first modern democracy' had an advantage over many countries also in that respect. As Alexis de Tocqueville (1805–59) wrote in his *Democracy in America* (1835–40), 'a new political science is needed for a world itself quite new' (Tocqueville, 1994: p. 12).

The Early Years of the Discipline of Political Science

The birth of political science as a discipline can be illustrated by comparing American and European trajectories in the study of politics. It is sometimes claimed that the first political science professorship was founded at the University of Uppsala in Sweden in 1622 (a professor of Discourse and Politics). However, a similar professorship had been founded at the Dutch University of Leiden already in 1613. Politics had also been taught at many German universities since the fourteenth century. It became an important subject of teaching at the Faculties of *Staatswissenschaft* (the sciences of the state) in the nineteenth century. Mainly for political reasons, the subject disappeared after the 1848/49 political upheavals. In the late nineteenth century, however, the teaching of politics was introduced as *Allgemeine Staatslehre* (the general theory of the state) at German law faculties. In that sense, the study of politics has been well rooted in European universities for centuries. However, before the World War II, it was conducted undifferentiated from neighboring fields, which later became disciplines, such as history, philosophy, and constitutional law (see the chapters in Klingemann, 2007).

At the beginning of the disciplinary development, American political science did not differ much from the study of politics in Europe. Teaching and research were based on European intellectual traditions. Francis Lieber (1798–1872), who has been called the first American political scientist (Farr, 1990), was a German, who had emigrated to the United States in 1827 after having studied in German universities (as well as being wounded at the Battle of Waterloo and participating in the Greek War of Independence in 1821). Starting his life in the United States as a swimming instructor, he became a Professor of History and Political Economy at the South Carolina College in 1835. In 1857, he moved to the Columbia College in New York, becoming a Professor of History and Political Science, the first time political science was recognized as part of an academic title. Through his career, Lieber had close relations with European scholars (being, for instance,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03042-7

one of Tocqueville's sources of information on American democracy).

Furthermore, around the turn of the twentieth century, hundreds of American PhD students went to study in Europe, mainly in Germany, and introduced German scholarship and teaching methods in American academia after their return (Haddow, 1939: p. 172). One of these 'exchange scholars' was John W. Burgess (1844–1931), who studied in Germany and France during 1869–73 and initiated a plan for the School of Political Science at Columbia College (later University). One of Burgess's main inspirations for the School was the *Libre Ecole des Sciences Politiques*, which had been founded in Paris in 1872 to train civil servants, diplomats, and journalists as well as to educate laymen in politics, economics, sociology, journalism, and law. The Columbia School was opened in 1880 and became an early center of the discipline of political science. Burgess himself became a Professor of Political Science and Comparative Constitutional Law. Because of the founding of the School, Burgess has often been taken as one of the founding fathers of political science (Somit and Tanenhaus, 1982).

The model of the *Ecole Libre* was imitated not only at Columbia, but in many European countries as well. Some of the new institutions which were founded included, e.g., the *Facoltà di scienze politiche* in Florence (1874), schools for political and social sciences at *the Catholic University of Louvain* and at the *Free University of Brussels* (1893), the *London School of Economics and Political Science* (1895), the *Ecole des Sciences Sociales et Politiques* at Lausanne (1902), the *Deutsche Hochschule für Politik* in Berlin (1920), and a *Higher School of Political Sciences* in Athens (1927) (see the chapters in Klingemann, 2007).

The early Columbia School reminded its European counterparts. The journal, *Political Science Quarterly*, which the Columbia School had begun to publish in 1886, manifested this well. It was a journal for political *sciences*, the articles were written as well by economists, historians, and public law scholars as political scientists. The focus of political science was on the study of the state. In the first issue of the journal, the managing editor Munro Smith wrote, "[t]he principal legal question of the day, in our country is: to what organ or organs of the state shall the development of law be trusted – to the judicial and legislative, or to the legislative alone? … Whether the increasing of the state be deplored or applauded, the fact remains that it is rapidly becoming, if it is not already, the central factor of social evolution" (Smith, 1886: p. 8). In the 1890s, the School developed into a Faculty with three internal groupings, 'economics and social science', 'history and political science', and 'public law and comparative jurisprudence'. The Department of Political Science evolved only later from the last of the three groupings (Somit and Tanenhaus, 1982).

If Columbia had close relations with German scholarship and public law, another important political science institution, the Johns Hopkins University, was influenced by historical scholarship and the Anglo-Saxon tradition. Johns Hopkins began its first semester in 1876. In 1882, a Department of Historical and Political Science was founded with Herbert Baxter Adams (1850–1901) in charge of the Department. In 1883, Adams started the book series, *The Johns Hopkins Studies in Historical and Political Science*, which was one of the first publishing outlets in the field of political science. Although also Adams had studied in Germany he was influenced more by the British historical scholarship.

Columbia and Johns Hopkins were the two main universities usually recognized as the 'founders' of political science as a discipline. However, there were similar developments in Cornell, the University of Michigan and Yale. Besides, the first separate political science department was created at the University of Chicago when it opened its doors in 1892. At the same time, Chicago established the separate departments of political economy, history, sociology, and philosophy.

Although the American and European study of politics did not differ much from each other intellectually in the late nineteenth/early twentieth century, organizationally American political science began to develop rapidly. By 1914, there were 38 separate political science departments at American universities. Political science was also offered in 216 departments with other disciplines (Anderson in Haddow, 1939: p. 263). The number of independent political science departments increased and with them the number of political scientists. The *American Political Science Association* (APSA) was founded in 1903. In 1904, the membership of APSA was 214, by 1920 it had increased to some 1300. Separate political science departments, a disciplinary association and specialized publications in the field (the first real political science journal, the *American Political Science Review*, was founded in 1906) made the study of politics a discipline in the United States, while in Europe it remained part of other academic subjects without any organized interaction between the students of politics.

Political Science after the World War I

Between the World Wars I and II, the American and European study of politics began to differ from each other intellectually. Political participation, political parties and groups, became a new focus of research in the United States. The study of the functioning of mass democracy required new research methods. Historical and judicial analyses were replaced by the use of current documents and first attempts to use interviews as data and statistics as a research method appeared. Psychology was seen as an important discipline to explain citizens' political activity. Other social sciences, especially sociology, were seen as allies instead of the old partners, history, and constitutional law. The department of political science at the University of Chicago under the leadership of Charles E. Merriam became an innovative center of the discipline focusing on *New Aspects of Politics* (Merriam, 1925).

Old concepts were replaced by new ones. Power gave a more dynamic view on politics than sovereignty. One of the theoretical innovations was the theory of pluralism. Although the concept had European roots, as it had been introduced earlier by such scholars as Leon Duguit in France and Harold Laski in England, in the United States it became a theory that emphasized group activity as the basis of politics. Pluralism focused on the limitations of state sovereignty and argued that the state was not the only unit in society, which commanded the allegiance of its subjects. More importantly, pluralism was used as a theoretical framework in empirical studies on political parties and pressure groups.

Empirical research also influenced a new theory of democracy, which later has been called 'the relative theory of democracy' (Purcell, 1973). It emerged as a response to national and international challenges. In the 1920s, American political scientists discussed the unforeseen tendencies of democracy, such as low political participation (nonvoting) and the role of special interests in politics. These tendencies did not fit well with the ideal of democracy. In the 1930s, American political scientists still faced another problem. The development of authoritarian political systems in Europe and in Asia posed a threat to American democracy struggling with economic recession. A new theory of democracy tried to solve these internal and external challenges. It was argued that nonvoting was not a problem, as it guaranteed the stability of the political system. Instead, the most important condition on democracy was a democratic culture, a common way of acting. Furthermore, a new theory praised the value of compromises in politics. Democracy was an agreement to disagree. There was no place for absolutes in politics.

The relative theory of democracy emphasized empirical research. However, it soon had to face a theoretical challenge, which was posed by European refugees, especially from Germany. Many of them represented philosophical traditions, which challenged the principles of the new American empirical research. These refugee scholars influenced theoretical discussion in American social science (e.g., Leo Strauss, Hannah Arendt, Max Horkheimer), but at the same time, they were creating a rift between the empirically minded and more theoretically oriented political scientists, leading into a division between empirical political science and normative political theory (Gunnell, 1993).

Political Science after the World War II

After the World War II, the model of empirical American political science was introduced in other parts of the world. For a number of reasons, the American influence was the biggest in Western Europe. The time was ripe for the empirical study of politics in many European countries, as many thought that a better understanding about politics could have prevented the catastrophe of the War. At the same time, UNESCO wanted to create international social science associations. Political science was one of the first of these (sociologists establishing their own international association at the same time).

The *International Political Science Association* (IPSA) was founded in 1949 under UNESCO's auspices although political science as a discipline hardly existed outside North America (Coakley and Trent, 2000). IPSA was designed as an association with collective members (national political science associations). However, in addition to the American association, only the Canadian (established in 1929), the Finnish (1935), the Indian (1938), and the Japanese (1948) associations were in existence. The Chinese association (1932) had become inactive during the war. At the beginning, IPSA had to rely on individual political scientists to be able to begin its activities. In the meeting, which drafted the Constitution in 1949, it was decided that IPSA would become into legal existence, when four national associations had joined it. This happened later in 1949 after the French association had been set up and became a founding member of the IPSA together with American, Canadian, and Indian associations. Other national associations followed. The first of these were established in the United Kingdom (1950), the Netherlands (1950), Belgium (1951), and Germany (1951).

At the beginning, most European scholars were skeptical about the American model, which emphasized the scientific study of politics as an independent discipline. In the late 1940s, the general opinion in Europe was that "[p]olitical science, as a distinct branch from speculation concerning political phenomena or the history of these phenomena, is of fairly recent development, more recent, certainly, than other social sciences such as law, political economy and sociology" (Salvadori in UNESCO, 1950: p. 1). Besides, there were differences between the British, French and German traditions in the study of politics. These differences were displayed also in other countries, as the British study of politics was influential in most Commonwealth countries (including India), the French legal tradition was followed in the Mediterranean countries, and even in many Latin American countries, while the German tradition of *Allgemeine Staatslehre* had followers in Austria, the Netherlands, Scandinavian countries, as well as in Japan (Coakley and Trent, 2000: p. 3).

The British scholars argued that the history of political ideas must have a prominent place in political theory and one cannot understand government without knowing its historical background and growth (Robson in UNESCO, 1950: p. 306). The best example of the British skepticism toward American political science was Bernard Crick's book *The American Science of Politics* (1959), which argued that the idea that politics can be understood by the method of the natural sciences is embedded in American political culture (Crick, 1959: p. v). On the other hand, French scholars thought that the term 'political science' is familiar mainly to scholars in the Anglo-Saxon countries. In France, one was used to understand the study of politics as part of the "political sciences", as "practically all of the social sciences could be qualified, at least in certain aspects, as political sciences" (Kopelmanas in UNESCO, 1950: pp. 647–648). Germans were more divided in their attitude toward the scientific study of politics as an independent discipline. The lost war had discredited the German scholarship and the study of politics was highly fragmented after the war. At the same time, some returning émigré scholars introduced American political science in Germany, which made German political science responsive to the idea of the scientific study of politics.

In spite of the early skepticism about the idea of political science as an independent discipline, the separate departments of political science were founded in many West European universities between 1945 and 1960. The pace of development varied, however, as the discipline took off first in northern Europe, where the old German *Allgemeine Staatslehre* tradition was replaced with the American model of political science. The British and German political scientists started to adopt American theories and methods only later. Close relations with American universities and the founding of new universities in both countries helped to move the discipline closer to American political science in the 1960s.

For cultural and organizational reasons the disciplinary development in France and in southern Europe was much

slower. The French political science has been a divided discipline with the majority of political science chairs at law faculties and the minority at eight *Institut d'Etudes Politiques*, where political science has often been understood as political sociology. Although the situation has changed, the idea of an independent political science discipline raises still opposition among some French quarters. Organizational difficulties have also hindered the development of Italian political science. In Italy, the first political science chair was established at the University of Florence as late as 1966. In Italy, political science has been part of the faculties of political sciences, where paradoxically the discipline has been a minor subject. The same organizational difficulties have been noticeable also in Portugal and Spain. Besides, because of the authoritarian political systems until the 1970s, the discipline has been able to develop in these two countries only since the 1980s (see the chapters in Klingemann, 2007).

The organizational development of the discipline has been still slower in the other parts of the world. The idea of political science as an independent discipline has been accepted in many countries only since the 1960s on (Jinadu, 1991 on Africa; Atal in Easton et al., 1995 on Asia).

American Behavioralism

The themes that had emerged during the interwar period in American political science developed further in the 1950s and 1960s. The discipline adopted a more systematic perspective on the study of politics. One of the early calls for a more scientific approach was David Easton's book *The Political System* (1953) which criticized American political science about hyperfactualism (empiricism without theory). The new political science was soon labeled as behavioralism. Dwight Waldo has expressed the change in the following way:

> By almost any measure the most important aspect of post–World War II political science has been the rise of 'behavioralism': the controversies it engendered, its success to coming to dominate much of organized political science, the changes it brought in the matters to which political scientists attend, and the manner in which they are addressed.
>
> (Waldo, 1975: p. 58)

The heyday of behavioralism was from the mid-1950s to the mid-1960s (Somit and Tanenhaus, 1982: p. 185). It was the main intellectual approach that 'Americanized' the study of politics in Europe and in the other parts of the world. Writing about European political science in the early 1990s, Ken Newton and Josep Vallès noted that "it is, nevertheless, true that the 'behavioral revolution' transformed large parts of political science in Western Europe, and its effects were so profound that some on the European side of the Atlantic claim that their traditions of political inquiry were abandoned or forgotten to such an extent that the American approach colonised the West European profession" (Newton and Vallès, 1991: pp. 234–235). Although Newton and Vallès see the colonization thesis as an exaggeration, they do not deny the American influence. This influence was also due to an increasing interest in comparative politics. American political scientists traveled around the world gathering data and trying to develop a cross-cultural theory of politics (see the chapters in Daalder, 1997).

In spite of its importance, behavioralism has not been easy to define. Most histories of political science agree that its origins are "somewhat obscure" (Waldo, 1975: p. 58) and "attempts at coming to any complete definition … are probably futile given the diversity of those who followed its banner" (Seidelman and Harpham, 1985: p. 151). However, one of the most influential definitions has been David Easton's list of the characteristics of behavioralism: (1) search for regularities, which can be expressed in generalizations or theories with explanatory and predictive value, (2) the verification of propositions by testable data, (3) the development of research techniques which can be used for the rigorous observation and analysis of behavior, (4) the precision of data and findings with quantification and measurement when possible and relevant, (5) keeping ethical evaluation and empirical explanations analytically distinct, (6) the systematization of research with theory and empirical research as intertwined parts of a coherent body of knowledge, (7) the application of knowledge as part of the scientific enterprise, but pure science preceding the application of knowledge, and (8) the integration of political science with other social sciences to analyze the whole human situation (Easton, 1965: p. 7).

One of the main dividing lines within behavioralism has been between those who conduct empirical studies based on surveys (mainly voting studies) and those who have wanted to develop theoretical (conceptual) frameworks for political analysis, such as systems analysis (David Easton), structural functionalism (Gabriel A. Almond), or cybernetics (Karl W. Deutsch). On the other hand, the most important empirical theory that emerged as part of behavioralism was the pluralist theory of democracy. One of its main early works was Robert A. Dahl's *Who Governs?* (1961). Dahl criticized the elitist conception of power (the existence of one power elite in society) and described politics as a struggle for power between many unequal elites. Different elites were making decisions in different policy areas.

Postbehavioral Revolution

In the end of the 1960s, the opponents of behavioralism launched a counterattack, which changed the contours of the discipline. Criticism arose from different sources, conservative, radical, and liberal. Conservative political philosophers were often unsatisfied with the results and ideology of empirical political science. The most outspoken critics were Leo Strauss and his followers, who accused behavioralism for relativism and for pretending to represent value free research while promoting liberal democracy (Storing, 1962). Another source was a heterogenous group of left wing academics, who founded the *Caucus for a New Political Science* in 1967 in response to the social upheavals of the times. Many of these scholars participated in the antiwar, civil rights, and feminist movements. The postbehavioral revolution included even liberals, often policy analysts hoping to make political science a more socially relevant discipline.

In 1969, it was David Easton again, who summarized the views of this heterogenous movement as postbehavioral revolution and identified seven of its tenets: (1) substance must precede technique, as it is better to be relevant and sometimes vague rather than nonrelevantly precise, (2) behavioral science conceals an ideology of empirical conservatism, (3) behavioral research has lost touch with reality, (4) research about and constructive development of values are part of the study of politics and one must be aware of one's own value premises, (5) political scientists bear the responsibility of all intellectuals to protect the humane values of civilization, (6) knowledge means the responsibility to act and to engage in reshaping society, and (7) the politicization of political science is inescapable as well as desirable (Easton, 1969: p. 1052).

The postbehavioral revolution ended the hegemony of behavioralism. However, behavioralism has not disappeared, but exists along new competing research traditions. Political philosophy, policy analysis, and various critical approaches, including historical institutionalism, have become strong research areas. In addition, since the publication of Anthony Down's *The Economic Theory of Democracy* (1957), rational choice theory has become a widely held paradigm in American political science. The theory has many variations, however, from the fiscal conservative public choice theories to William H. Riker's studies on voting and group behavior and to a Nobel laureate Elinor Ostrom's *Governing the Commons* (1990). These developments have led to the fragmentation of political science into competing theoretical schools.

Fragmentation of Political Science

As the history of political science shows, the development of the discipline has proceeded through continual attempts to legitimize and delegitimize various research traditions. In that sense, it is no wonder that the so-called *Perestroika* movement emerged in 2000 to oppose the strong position of rational choice theory in American political science (Monroe, 2005). The movement criticized the elitist nature of the *American Political Science Association* with its white and male leadership. It also criticized the irrelevancy of the *American Political Science Review*, which was seen to contain mainly articles based on statistics and game theory, while ignoring articles based on other research methods. The revolt has led into a more pluralist American discipline, as the APSA has responded to criticism by renewing its decision-making procedures, encouraging qualitative research and offering new publishing outlets to its members. The change has vitalized the discipline, but at the same time it has become still more fragmented into different theoretical schools.

The American postbehavioral revolution coincided with the strengthening of the discipline in Western Europe. The *European Consortium for Political Research* was established in 1970 (Newton and Boncourt, 2010). This has led to an increasing cooperation between European political scientists and for further growth of the discipline. The breakdown of the European communist regimes in 1989/91 has also changed the landscape of political science (Eisfeld and Pal, 2010). Still in 1982, the editor of the *International Handbook of Political Science*, William G. Andrews (1982: p. 3), estimated that the American political scientists represented 75–80% of the world's supply. Recently, however, Hans-Dieter Klingemann (2008: p. 376) has estimated that around 2005 there were some 10 000 political scientists in Europe, half of them being in the Central and Eastern Europe. That roughly equals the number of American political scientists. Besides, the growth of the political science profession has been impressive in Asia during the last 30 years. There are some 5000 political scientists in Japan and some 2500 in South Korea alone (Inoguchi, 2012: p. 17). In addition, India has a long tradition of political studies. The discipline has developed rapidly also in Latin America during the last two decades. Although there are no exact figures available, it is safe to say that the increase of the number of political scientists around the world during the past 30 years has made political science a global discipline and diminished the previous central role of American political science in the profession.

Especially many European scholars have influenced theoretical discussion in the social sciences all over the world. German critical theory (Jürgen Habermas), French philosophy and sociology (Michel Foucault), as well as British intellectual history (Quentin Skinner) have opened new perspectives also for the study of politics. There are no paradigmatic theories in contemporary political science, but many competing theories and intellectual cultures. The globalization of the discipline has increased the diversity of theoretical perspectives. Different countries have their own intellectual traditions and scholars have become aware that they have to take into account local as well as global conditions when explaining politics. A good example is a study of democracy. There is no single theory of democracy today. Instead, the theories of deliberative, participatory, delegative, cosmopolitan, and global democracy, among others, are offered as solutions to the problems of contemporary politics.

The fragmentation of the discipline is displayed by the growth of different subdisciplinary specialties. Many scholars identify themselves more as members of a specific research field than as political scientists in general. International relations and public administration have founded their own associations and journals, and especially the study of public administration has in many countries cut itself off from the rest of political science. The identity politics has also become important, especially in regard to gender and race. Feminist political theory has become one of the fastest growing fields within political science.

Globalized Political Science

This historical account has focused mainly on the United States and Europe. This can be justified by the fact that the birth of political science as a discipline has been closely linked to the American and European scholarship. One cannot deny the organizational and theoretical influence of American political science in other countries (Inoguchi, 2012: p. 11). Since the 1970s, also European political science has grown in importance. This is not to deny the role of political science in other parts of the world. However, political science is still an unevenly developed discipline worldwide. One of the signs of this is the existence of political science associations in the world

and their membership in the *International Political Science Association*. Currently (2013) there are 51 collective IPSA members, 31 of them are from Europe, 2 from North America, 3 from Africa, 8 from Asia, 6 from Latin America, and 1 from Oceania. However, the change in that respect is evident in the future, as recent developments in Asia and Latin America show. Political science has become an international discipline, but it has not reached its limits yet.

This article is a revision of the previous edition article by E. Allardt, volume 17, pp. 11701–11706, © 2001, Elsevier Ltd.

Abstract

Political sociology is a major subfield on the border of sociology and political science, combining explanatory factors and research interests of both disciplines. It developed from the work of the early founders of social science to include areas of inquiry that tackle the salient social and political processes of the twentieth century and the contemporary world. We discuss important theoretical and empirical advancements and the subfield's continuous preoccupation with the interrelationships of 'politics' and 'society', political and social changes, and with issues of power, domination, and exploitation.

Political sociology bridges the fields of sociology and political science by addressing issues of power and authority with a focus on state/civil society relations. Political sociology differs from political science in that it includes and often focuses on the civil society side of the equation rather than placing an emphasis on the state and/or political elites. Core areas of research include state formation and change, forms of political rule, major social policies, political institutions and challenges to them (including reform-oriented and revolutionary social movements), political parties and the social bases of political attitudes and behaviors, class/power relations, and the political consequences of globalization. The field includes distinct major approaches, yet theoretical combination and synthesis is common. Many early and contemporary studies utilize comparative historical analysis, especially with regard to critical junctures and historical processes and developments, whereas current work has become methodologically more eclectic. Contemporary political issues and events, regimes in power, and cases relating to the United States and Europe tend to garner the most scholarly attention, though there is a steadily growing body of theory and empirical work beyond the core capitalist democracies.

We consider four somewhat distinct periods in the development of political sociology, while prioritizing the most recent period: (1) We trace political sociology's inspiration in the mid-nineteenth century to the earlier philosophers who considered the state and social life, but note that it was not until the founding fathers of nineteenth-century social science began thinking of society and the state as distinct entities and analyzing the relationships between them, that political sociology was born; (2) The post–World War II period, which shifted the subfield's focus to the prerequisites of democracy and voting patterns; (3) The late twentieth-century period, which saw political sociologists move toward a focus on state building and political change, using Marxist theories of capitalism and class as well as other theories; and (4) The contemporary period, which is characterized by a proliferation of topics relevant to politics such as globalization, race, gender, and culture. (Sections Historical Developments through Mid- and Late Twentieth-Century Period are largely abridged, paraphrased, and enhanced versions of the previous survey by E. Allardt in this publication. See Allardt (2001) for full references to these sections. Additionally, for broad works on political sociology, see Alford and Friedland, 1985; Janoski et al., 2005; Amenta et al., 2012.)

Historical Developments

The foundations of social sciences emerged in a context of epochal social and political transformations, including the development and unfolding of capitalist social systems and the modern state. These developments encouraged conceptualizations of the state and society as separate entities, making it possible to investigate their interrelations. Relying on earlier works on social life and politics by philosophers, historians, and legal theorists, sociology's three founding fathers made important contributions to political sociology's beginnings. Karl Marx challenged the idea that power concentrates solely in political offices and officeholders. Instead he focused on politics as emerging primarily from class conflict, just as the bourgeoisie and industrial working classes were becoming the principal social groups. He also emphasized the role of ideology in sustaining the powers that be. Max Weber responded to and critiqued Marx and added important analyses of authority, status categories, and social institutions (especially bureaucracy). Sociology's third founding father, Emile Durkheim, did not have an explicitly political focus, yet his emphasis on social order, integration, and solidarity had important implications for analyses of society and politics. Others more directly associated with the emergence of political sociology include: Talcott Parsons, who was inspired by Durkheim, Vilfredo Pareto, and Gaetano Mosca, who made independent contributions by emphasizing the role of elites for social and political change (along with others who continued this concern, including Robert Michels, C. Wright Mills, G. William Domhoff, Alexis de Tocqueville, and Seymour Martin Lipset).

Marx and Class Domination, Capitalism, and Revolution

Marx was among the first to articulate an empirical political sociology, marking out historical materialism in his systematic general insistence on exploring the relationships between the mode of economic production and social property relations with state/political forms, social and political struggles, and consciousness, with a particular focus on capitalism and classes

in capitalist societies. His was a firmly historical sociology, which emphasized human agency and historical contingency as being conditioned and constrained by structural features and processes, and consequently critically analytical of the character and dynamics of capitalism. Broadly, Marx argued that the division of societies into social classes is based on objective relations of domination and that the dominant class' exploitation of dominated classes is central to many historically specific forms of economic production. In such situations, the state or central political power and authority generally maintains and reproduces the basic social systems, which are riven by the potentially explosive or revolutionary social antagonisms rooted in these relations of domination and exploitation. Despite varying and often contradictory interpretations of his extensive body of work, Marx's framework is often seen as the primary source of political economy and class approaches.

Like Marx himself, several later Marxists had wide-ranging influence both in and outside of academia. Vladimir Lenin developed theories on revolutionary politics and change, imperialism, the state, and liberal democracy. Leon Trotsky's work on the Russian Revolution is a milestone in scholarship on revolution and historical sociology, prioritizing mass political participation and the study of the political processes of the masses themselves in relation to political leaders and parties. He emphasized the historical unfolding of revolutionary struggles and the necessity of analyzing the structural conditioning, if not constitution, of such intense sociopolitical struggles in forms of economic development (hence the theory of combined and uneven development). Antonio Gramsci offered influential theories on hegemony, political conflict, and the distinction and relation between political society and civil society in capitalist democracies. Central to his work was the notion that bourgeois cultural values and institutions, (both those centered in the state and those that were not), help create situations of consented coercion, with continuous state formation acting to balance the interests of the 'fundamental group and those of the subordinate groups'. These analyses demonstrate that political sociology includes politically-oriented analyses, and also that important historical actors are included as political sociologists.

Weber and Political Authority, Bureaucracy, and the Modern State

Max Weber wrote many of his works in response to Marx, with considerable overlap and agreement as well as divergence. Also largely historical, Weber traced the "elective affinity" of capitalist development and Protestantism in Europe, highlighting their functional compatibility and the eventual coconstitutional development of economic forms with culture and ideology. Additionally, Weber's work examined ideal typical forms of legitimate authority and domination, bases of individual and group social action, and perhaps most important, he offered a general theory of rationalization (i.e., instrumental rationality) as embodied in bureaucratic organizational forms and the wide-ranging bureaucratization of modern life – the latter process tied into the dynamic development of capitalism and the modern state. In contrast to Marx, who saw the modern state more or less in relation to powerful class interests, class struggles, and capital accumulation processes, Weber emphasized the modern state as an autonomous source of interests and power. Cultural scholars at times refer to Weber's wide-ranging body of work and theory, yet his work is more often than not associated with and taken as a basis for statist approaches.

Many theorists have been influenced by Weber, including those who furthered the study of elites and bureaucracy. Vilfredo Pareto and Gaetano Mosca were pioneers in the sociological study of elites. Pareto identified the governing elite, who ruled with a psychological preference for either force or fraud. He argued that the elite class is maintained by the circulation of especially apt nonelites into the ruling group. Mosca takes a more sociological approach to the study of elites by emphasizing structural and organizational factors in the maintenance of elite classes, such as their superior organization and their control of resources.

Robert Michels' seminal work criticized party bureaucracies in modern states and addressed central themes such as the role of elites, leftist political movements, bureaucratization, and the gap between democratic theory and practice. Michels developed a thesis called "the iron law of oligarchy", which argues that organization necessarily leads to oligarchy. In Michel's words: "it is organization which gives birth to the dominion of the elected over the electors, of the mandataries over the mandators, of the delegates over the delegators. Who says 'organization', says 'oligarchy'" (1911/1968).

The Durkheimian Tradition and Pluralism

While Marx and Weber were clearly social and political theorists, Emile Durkheim is less often noted as a scholar of politics. However, his concern with social order, integration, and solidarity had clear implications for analyses of politics and society (Allardt, 2001). Durkheim attempted to overhaul the traditional concept of an increasing division of labor and social cohesion, in his insistence that modern societies can achieve a degree of cohesion surpassing their predecessors. He is often associated with those who emphasize culture, values and norms, and functionalism, with a linkage to later pluralist theorists that would come to dominate American social science.

The English translations of Alexis de Tocqueville's *Democracy in America* and *The Old Regime and the Revolution* are standards in political sociology. In the former, he specified the conditions for pluralism and institutional democracy, arguing that in industrially developed societies, social cleavages, and group/strata competition are necessary for consensus. Plural democracy is created and sustained by voluntary associations and active, relatively autonomous local communities. Thus, de Tocqueville emphasized the role of social conflicts and cleavages in developing consensus in democracies (Allardt, 2001).

The Institutionalization of Political Sociology after World War II

In the postwar period, the prerequisites of democracy and the role of parliamentary elections as the major mechanism for establishing and securing democratic rule became important foci. After the war there were great hopes attached to the

possibility of building a better world with the aid of social science and research. As political science became more preoccupied with constitutional problems and modes of state management and sociology focused on social structure and social group behavior, political sociology moved between the disciplines (Allardt, 2001).

Political sociologists undertook large-scale studies of voting behavior and developed fruitful theories and hypotheses, such as Lazarsfeld's argument that cross-pressures lead to political passivity (Lazarsfeld et al., 1944; Allardt, 2001). Seymour Martin Lipset had already published important works, and his *Political Man: The Social Bases of Politics* (1960) became a leading text of the period and helped give birth to institutional political sociology. Lipset's and Rokkan's *Party Systems and Voter Alignments: Cross-National Perspectives* (1967) would later apply Parson's A-G-I-L scheme (an analytic model designed to explain stability by considering Adaption, Goal Attainment, Integration, and Latency) in an attempt to combine structural and institutional approaches to understand the social bases of politics and the effects of politics on social structures (Allardt, 2001).

It was in this context that the pluralist conceptualizations of social and political action arose in earnest. In this vein, Smelser emphasized the state, collective behavior, and cultural-value change (1967); Easton focused on the political system (1965); and Gurr on political violence and relative deprivation (1970). Broadly, these studies tended to equate the political system with the state and considered individuals with distinct preferences and values to be the constitutive units of both organizations and societies (Alford and Friedland, 1985: p. 35).

While the study of electoral behavior and voting patterns became a specialized area of inquiry, political sociologists' basic interest was in studying the conditions for democracy, regime type and breakdowns, state and nation building, modernization, and other processes of social and political change (Allardt, 2001).

Political sociologists, for example, have explored many aspects of democracy: the conditions for democracy in labor unions (Lipset et al., 1956), in the local community (Robert Dahl, 1961) and the conditions of conflict regulation in industrial society (Dahrendorf, 1959). Others focused on the breakdown of democracy and the rise and appeal of Fascism and Communism, such as Raymond Aron in *The Opium of Intellectuals* (1955) and William Kornhauser in *The Politics of Mass Society* (1959). C. Wright Mills *The Power Elite* (1990) examined the relationships and shared interests among US corporate, political, and military leaders; leading to the concentration of economic power and cultural influence in the hands of the relatively few and interchangeability of positions within these three institutions.

The Mid- and Late Twentieth-Century Period

With the maturity and incorporation of electoral studies and studies of some other original political sociology topics in the 1960s and 1970s along with new critiques from the left, these topics disappeared from political sociology's central agenda. Increasingly, the focus became large-scale patterns of societal change. S.N. Eisenstadt (1963/1993) examined the formation and fall of empires, Rokkan studied the historical formation of European centers and peripheries (Rokkan and Urwin, 1983) and Juan Linz analyzed the breakdown of democratic regimes (Linz and Stepan, 1978) (Allardt, 2001).

Yet the period was perhaps most substantially marked by the outpouring of Marxist or Marxist-oriented scholarship on class politics and major sociopolitical transformations as well as the structural contours and dynamics of global capitalism (Allardt, 2001). Unfortunately a full review of this literature is not possible, here, and thus several important examples must suffice. Barrington Moore wrote an often-quoted major work *The Social Origins of Dictatorship and Democracy* (1966), using in-depth historical case studies to show how the varying class coalitions that emerged during agricultural commercialization impacted the forms of 'political modernization' in the modern world. E.P. Thompson (1963) explored workers' life experiences and cultural outlooks in his historical analysis of the formation and consciousness of the British working-class. Jeffery Paige (1975) explored how specific agrarian organization and class relations encouraged certain forms of political action and revolution. Maurice Zeitlin (1984) and Zeitlin and Ratcliff (1988) analyzed the development of the Chilean state in light of struggles between segments of the dominant class and the interactions between international and domestic forces. G. William Domhoff (1967, 1990) combined class and institutional analysis to build his class dominance theory and explore how the power elite in the US (owners and top managers of major corporations) actually dominate policy-making. Immanuel Wallerstein (1974/2011) focused on international divisions of labor in his study of the origins and structural contours of the world capitalist system. On the borders of political sociology were the critical sociologists in the Frankfurt School of dialectical sociology and the Dependency theorists who pointed out how underdeveloped countries were enmeshed in a world dominated by international capitalism.

Interest in master patterns of change and in state and nation building proliferated in the 1980s and 1990s. Theda Skocpol (1979) helped reintroduce the state as the originator of social outcomes and Charles Tilly (1992) stressed a complicated web of warfare, fiscal policy, bureaucratization, and state-making as forming national developments. Goran Therborn's (1995) studies of European states emphasized that national development is multidimensional and may be reversible.

Developments from this period onward made the borders of political sociology more permeable. For instance studies considering the roles of ethnicity, ethnic groups, and ethnic identities in the formation of nations straddle the line between political sociology and race/ethnic studies. Studies in the political sociology tradition often emphasize the macro-level role that ethnicity and ethnic identities may play in the formation of nations and political development (Rokkan and Urwin, 1983).

The Contemporary Period

Over the last few decades, scholars have expanded political sociology's theoretical and empirical scope. Established approaches have persisted and developed, and have been challenged or supplemented by theories of rational choice (Tsebelis,

1990; Chong, 2000), culture (B. Anderson, 1983/2006; Bourdieu, 1984/2013; Inglehart, 1997), race (Gilroy, 1991; Winant, 1994), gender (Orloff, 1993; Paxton et al., 2007), and several institutionalisms (Amenta and Ramsey, 2010; Thelen, 1999). Oftentimes, these approaches influenced political sociology after migrating from political science, economics, or the humanities. While 'new' theoretical perspectives and explanatory models may initially seem to displace established approaches, their overly bold early claims may recede as scholars implicitly or explicitly adopt theoretical synthesis or accommodation, or bolster their approaches by accounting for or appropriating salient factors or processes emphasized by others. So, while Marxist scholarship which flourished in the 1970s lost much of its early fervor by the mid 1980s, political sociology has remained theoretically eclectic.

Scholars are also more likely to explore historical or contemporary empirical phenomena of diverse geographical settings, a trend bolstered by the growing numbers and diversity of academics and research institutions worldwide, e.g., political sociologists regularly examine social and political processes in cases outside of Europe and the United States. Further, not only do emergent and changing social and political circumstances tend to impact what is being explored (by providing cases) but also salient political trends and/or the configuration of political power holders may impact the explanations given.

Moreover, recent scholarship has benefited from methodological advances. While quantitative methods may predominate in the social sciences, the flourishing of work in comparative and historical methodologies (Abrams, 1982; Ragin, 1987; Mahoney and Rueschemeyer, 2003) has found fertile ground in political sociological research, both through within-case analyses and cross-case comparisons.

In this context, the following section not so much adjudicates theories but instead introduces empirical studies covering a range of research questions asked by scholars from different theoretical traditions. It is not an exhaustive review of recent literature; rather, it provides a brief look at some vital political sociology research areas, such as states and society, revolution, globalization, culture, immigration, macro-social theory, and also notes other substantive themes.

Scholarship on state formation continued in the decades after World War II, exploring processes of the formation of early modern European states, the global diffusion (uneven and varied) of their general political models, variations in regime type, welfare state formation, developmental states, and so on. While states differ along multiple axes, including over time and place, it is commonly held that national states originally emerged in early modern Europe (along with capitalism) and have thus received due diligence to the degree that it was from this temporal and geographical source that they exerted extensive gravitational pull on world history, so that state formation processes in later centuries – often accompanying Western imperialism – were reproduced across the globe as approximations of a single model. More generally, scholars explore modern states' formation with varying emphases on processes of capitalist development, war, international relations, resource extraction, class or elite coalitions, and culture.

Political sociologists emphasize the ways in which social factors impact state formation processes, considering capitalism and class as well as culture and institutions. Seminal Marxist explanations focus on rural classes and capitalist agricultural development to explain the origins of liberal democracies and Communist or Fascist dictatorships in major states (Moore, 1966); or investigate the centralized states of European Absolutism, its regional variation, and its role in the transition from feudalism to capitalism (Anderson, 1974/2013). Tilly (1992) adopts a bellecist approach to explore the formation of national states in an environment of incessant military-strategic competition, and system-wide convergence on that model in Europe. The interplay of war making, state making, and capitalist consolidation, Tilly argues, proceeds in a dialectic of the increasing concentration and accumulation of capital and coercion, pressed by war making and preparation, fiscal extraction, administrative expansion, and the making of social alliances. Ertman (1997) prioritizes local political institutional path dependency and the timing of the onset of sustained geopolitical-military competition, to account for the diverse range of regime types and state infrastructures across Europe in the eighteenth century, whereas Gorski (2003) shifts to culture to unravel the emergence of strong centralized states in Germany and the Netherlands, arguing that Calvinism and its emphasis on public order and discipline heightened state capacities and functions, regarding education, crime and punishment, and military effectiveness.

While extending insights from European cases to other regions, scholars often avoid transplanting some universal European trajectory and note the impact of colonialism, Western geopolitical dominance, and how being 'late' developers may impact state formation in the Third World. Heydemann (2000) notes that interstate war between Middle Eastern and North African states was rare in the twentieth century, but that extensive war preparation and militarized government produced deep political consequences, with variation in state formation linked to discrete modes of resource extraction. Centeno (2003) likewise describes interstate warfare as rare in post-independence Latin America, and argues that this absence corresponds to the weakness of Latin American states and the national elites' unwillingness to ally with them.

Scholars also study the development of welfare states and public social provision, the emergence and character of such systems, and/or their perceived ongoing decline in neoliberal capitalism (see Marshell 1950; Korpi, 1983; Huber and Stephens, 2001; Pierson, 1994). In general, political sociology emphasizes social inequalities along various dimensions and their impact on welfare states. Esping-Andersen (1990) explores the origins and role of welfare states in European capitalist countries, emphasizing the impact of working class power and varying class coalitions on the character of welfare states and regimes of public social provision. Fox (2012) explores the American social welfare system and how different racial and immigrant groups receive differential access to social welfare programs, whereas Misra (1998, 2003) analyzes family allowance policies, and the role of women's movements and the perceived value of women's paid and unpaid labor for variations in public social provision. Venturing to the global South, Sandbrook et al. (2007) look at social democratic movements and democratic developmental states, and how some peripheral states have balanced the achievement of economic growth through

globalized markets with relatively progressive social and political policies.

In a world of stark international inequalities, studies of development attempt to unravel the social and political processes behind prosperous economies with a focus on class relations, the state, and economic institutions. These works often center on the concerted efforts of post–World War II 'developmental' states, traversing state building, economic development, and postcolonialism. A major thrust in this literature explores conditions in which states and state leaders gain the wherewithal to ignite and sustain industrialization. One broad statist explanation focuses on state capacity and autonomy to guide and discipline capitalists (and labor), thus bolstering state planning agencies to drive developmental policies (Amsden, 1989; Evans, 1995; Wade, 1990). Some challenge, or refine, this state autonomy/capacity thesis. Chibber (2003) brings back in structural political economy to consider class alliances and interests, state capacity and autonomy, and international economic opportunity to explain situations where local capitalists gain from, and thus support, the strengthening autonomous state economic planning agencies (as in South Korea) and, conversely, (in cases where capitalists would suffer from, and thus stifle these institutions), robust development agencies and planning (as in India). His study illuminates crucial class and state processes impacting relative success versus relative failure, and deepens the understanding of capitalist classes in developmental states. Finally, Mahoney (2010) studies the impact of colonial arrangements on postcolonial development, and how institutional fit (or non-fit) between colonizer and colonized greatly influenced longer-term economic development.

Recent scholarship on revolution has shifted focus from the 'great' social revolutions (Moore, 1966; Skocpol, 1979) to political revolutions and revolutionary movements, and their varying forms and outcomes, in the post–World War II world. Political sociologists emphasize social compositional factors, regime types, and socioeconomic structure. Parsa (1989) offers a sophisticated articulation of the multi-class coalition thesis, arguing that the 'success' of the Iranian revolution was rooted in multiple social classes mobilizing in a common oppositional front outside the formal power structure of the Shah's autocratic regime. Accepting the import of class struggle, Goodwin (2001) refines a statist approach in his study of revolutions in Latin America, SE Asia, and East Europe, arguing that particular neopatrimonial state-regime types may not only incubate and encourage revolutionary movements but also impact the success of such movements in engendering political revolution. In a cultural turn, Slater (2009) holds that the political posture and emotive appeals of communal elites – those with religious and cultural authority – determines the emergence and outcome of revolutionary mobilization. Finally, Achcar (2013) extends and modifies Marx's theory of social revolution to analyze recent uprisings in the Arab world, arguing that it is the specific modality of an economic mode of production, especially in the political and legal structures that block social and economic development, rather than the generic economic mode itself, that may provide crucial causes for popular uprisings and thus become the object of political revolution.

Globalization naturally attracts considerable scholarly attention, providing numerous areas of inquiry. Political sociologists tend to focus on power relations in global capitalism and the consequences for development, the political institutions that undergird attendant policies, as well as salient spatial and organizational transformations. Dependency scholars Cardoso and Faletto (1979) critique Modernization theory's universal linear stage model of development, and prioritize asymmetrical and partially constitutive international power relations and their affects on national political and economic development. The world-systems tradition has long analyzed national and regional development in the light of the character and dynamic of global capitalism (Wallerstein, 1974/2011) and imperial hegemonies (Arrighi, 1994); yet many drop a level of analysis to examine crucial shorter-term political processes linked to a globalizing world. Babb (2009) explores institutional linkages between the American state (especially the legislative branch) and multilateral development banks, and Washington's political sway over them. Others explore China's rise and how it has helped reshape the structure and dynamics of global capitalism, as well as its geopolitical impact on China's close neighbors (Hung, 2009), global cities (Sassen, 2001), international organizations (Boli and Thomas, 2003), and so on.

Relatedly, neoliberal globalization, many argue, fundamentally includes financialization and attendant transformations that diminish the quality of public social provision, and political sociologists have analyzed multiple facets of these phenomena. Tabb (2012) investigates the restructuring of capitalism from the 1970s onward, specifically with regard to banking practices, financial motives, and regulatory policies. Krippner (2011) studies the historical development of the US financial market and the creation of market policies conducive to financialization, arguing that these were not policymakers' deliberate goals but the inadvertent results of attempts to solve pressing economic problems. Prechel and Morris (2010) explore the causes of financial malfeasance from 1995 to 2004 and how certain social structures create dependencies, incentives, and opportunities to engage in such behavior, i.e., neoliberal policies permit such activities, and largely result from well-financed and systematic corporate political strategy.

Immigration and citizenship in the globalizing world continues to capture scholars' attention, with the migration of people across countries clearly linked to potentially salient social, political, and economic transformations. Portes and Rumbaut (2006) provide a prominent overview of immigrant social and political dynamics in the US, honing in on micro- and macro-level processes impacting immigrants' individual lives as well as the wider social and political formations to which they belong. Bloemraad (2006) queries how countries that allow the entrance of immigrants and refugees can foster civic cohesion and political community, and tempers the widespread emphasis on features of immigrant communities by considering the impact of state policy for outcomes of citizenship acquisition and political participation. Furthermore, the global salience of 'market fundamentalism', argues Somers (2008), subjugates notions and practices of citizenship to market logic and yields deleterious results for people's lives.

Scholars continue to investigate social bases of politics and political behavior, which has been a hallmark of political sociology since at least the 1950s. Domhoff (1990) and Domhoff and Webber (2011) refine the class dominance theory to look at social networks of power and the role of capitalist class segments on the origins of major social policies; while Manza and Brooks (1999) consider more broadly the role social group cleavages have on electoral politics. Clawson et al. (1998) investigate the role of financial contributions in policy formation, and the relationships that may develop between politicians and private contributors. Scholars in this general line of inquiry also explore issues surrounding political parties (Panebianco, 1988; Shefter, 1994), public opinion (Dalton, 2008), and interest groups and other political organizations (Wilson, 1995).

The concept of culture is not only disputed in terms of its specific meaning(s), but it is also broad, multifaceted, and at times muddled, with cultural studies of politics employing the concept in wide-ranging and varying ways. Using a dynamic theoretical framework, Campbell (1998) explores how ideas – paradigms, public sentiments, programs, and frames – may influence major policy-making innovations. For Ermakoff (2008), subjective orientations and patterns of interactions impact major political change and the surrender of democratic to nondemocratic authority, while Ikegami (2005) details the interconnections of arts and esthetics with state–society relations in a case of state formation where esthetic socialization compensated for state policies that fostered extreme social fragmentation. Others explore folk music's unifying and galvanizing power, and the relation between cultural forms and social or labor movement activities (Roscigno and Danaher, 2004). In a different vein, important studies of the media examine the mass media in multiple ways, seeing a powerful and effective ideological institution that props the political status quo (Chomsky and Herman, 1988/2008) – society's "master arena" where individual or collective political actors engage in contests over social meanings (Gamson and Andre, 2004), the interactions of media discourse and public opinion formation (Gamson and Modigliani, 1989), and the news media as a political institution (Schudson, 2002). Also, in an ambitious macrophenomelogical approach and in macro-social theory, the world societal perspective prioritizes global culture in the production and spread of ideas, policies, and institutions (Meyer et al., 1997).

Other than world-systems scholars (Wallerstein and Arrighi), Michael Mann (1986, 1993, 2012, 2013) is one of the few contemporary political sociologists who attempts to rigorously identify the principal social-structural trends across history and to explain the development and expansion of fundamental power structures. Mann proposes the IEMP model, which holds that human societies form around four power relations – ideological, economic, military, and political – that are intertwined although none is purely reducible to another. For Mann, contemporary globalization is the "plural extension" of these four relations, with the primary modern power organizations (capitalism, nation-states, and empires) congealing around them. This globalization thus consists of three main institutional processes, the globalization of capitalism, the nation-state, and empires (eventually just the American empire). These processes, however, crystalize in various, often-competing forms and have thus been geographically and institutionally polymorphous.

Concluding Remarks

Certainly there are remarkable areas of social and political inquiry not included in the above survey, and even those discussed are only briefly introduced. There are veritable literatures on the political processes of empire and imperialism (Harvey, 2003; Wood, 2005), nationalism (Breuilly, 1994; Hobsbawm, 1990), labor and labor movements (Stepan-Norris and Zeitlin, 2003; Fantasia, 1989), ethnicity and ethnic conflict (Varshney, 2003; Gutiérrez, 1995), and so on. Nonetheless, there are several clear features or trends that manifest in this survey. Political sociology literature continues to emphasize civil society and potentially vital socioeconomic factors, in contrast to much of political science. With the aid of methodological advances, political sociologists continue to develop various theoretical frameworks and to expand the substantive breadth and depth of this border field. Scholars enter empirical cases from differing levels of analysis to address an inherently wide set of questions. With these diverse research approaches, political sociologists continue to cultivate useful knowledge through rigorous empirical research on social and political change as well as the basic problems afflicting societies, and thus remain relevant to policy-oriented debates. Echoing the previous entry from the first edition, political sociology's main general problem areas continue to revolve around the origins, character, and practices of social and political power and conflict; dominant and emerging cleavages; patterns of social, political, economic, and cultural change; the formation of states and nations as well as the breakdown of social and political orders; the conditions of different regime-types (e.g., democracy or authoritarianism); capitalist development; and multifaceted international relationships. For better or worse, these are vital areas of inquiry that will continue to provide attendant puzzles and problems to be scrutinized by political sociologists.

Abstract

Historically, the focus of political thought has been on a triad of related problems, namely those of constituting a community bound by a normative order, of establishing the legitmacy and terms of enforcement of such an order, and of articulating criteria for allocations of resources and entitlements. In early modern Europe political thought was largely concerned with the nature and legitimacy of new forms of normatively binding orders and their terms of enforcement. The concern with the constitution of political community became the central one in political thought from Hobbes and Pufendorf over Locke all the way to Rousseau. The intellectual transformation of the late eighteenth and early nineteenth centuries entailed a shift in the thinking about human beings, about society, and about the very nature of political order. The end of World War I and the interwar years marked the triumph and crisis of liberal political thought and the emergence of a range of forms of political thought that transcended liberal traditions. The history of political thought towards the end of the twentieth century has been characterized by efforts to reconceptualize the nature human agency, whether in a rationalistic-deliberative form or in a linguistic-interpretative form. The first stream of research has led to formulations of the nature of political community in contractual terms. It has also sought to establish normative criteria for the proper allocation of resources. The second stream has resulted in programs for the writing of conceptual and contextual intellectual histories. It has also involved efforts to position political thought in a wider global context.

Reflection about political phenomena in a wide sense of the term is as old as human community itself. It focuses on a triad of related problems that might be broadly delimited as follows. First, there is the problem of constituting a community bound together by a normative order, secondly that of establishing the legitimacy and the terms of enforcement of such an order, and, thirdly, that of finding criteria for a proper and just allocation of resources as well as of entitlements. Jointly these three sets of problems entail that political theory and the history of political theory, as distinct from, say, a theory of scientific validation or a theory of argumentation, will be characterized by an inherent duality. Thus it will not only, as these other types of theory, be an account of rules of contestation and signification. It will also have to involve an account of which such rules are and which are not upheld by a normativity that is, in the last instance, enforceable by violent means. Put in everyday language, political theory will in its core be a theory both about meaning and communication and a theory about power, enforcement, and, ultimately, violence. It is easy to see that different political theorists have come to emphasize different strands in this duality, but the duality itself is irreducible and constitutive of political thought.

Political Thought in Historical Context

Thought about such matters is found in clearly articulated form from the middle of the first millennium BCE onwards in all the major civilizations of Afro-Eurasia. Thus it is manifested in written texts in the sixth century by Confucius and two centuries later by Mencius, in China and the writings during the same period in India, as well as in the prophetical age of Jewish religion and during the era of classical philosophy in Greece. The emergence of imperial-like political orders across Afro-Eurasia in the last centuries of the first millennium BCE also gave rise to a range of texts about the nature of political order. This is equally valid for texts about the Roman and Byzantine empires in the Mediterranean region to texts highlighting features of rulership in Parthian and later also in Sassanian Persia, in Maurya India, and in the Han Empire of China.

The recording of political thought in the form of the writing of histories of such thought is however a much more recent phenomenon. At its focus it is the relationship of community-wide rules to forms of enforcement and an effort to arrive at an understanding of the historical context in which particular types of such relationships occur. The emergence of clearly articulated forms of historical thought is largely coterminous with the emergence of history and social science as forms of scholarly activity performed within reformed or newly created universities and higher education institutions from the early nineteenth century onwards. In order to understand the key features and characteristics of the writing of histories of political thought it is first of all necessary to bring out key conditions of political thought in the region in which such an early disciplinary condition first occurred, namely in Europe.

Political Thought and Early Modernities

In a broad sense political thought in early modern Europe was a way to understand the nature of ruling in human communities and to grasp the conditions of normative argumentation and enforcement in such communities. The need for new understandings of these types of phenomena was itself directly related to the gradual decline and eventual demise of the two most prominent institutional forms of medieval Europe. Those were, first, the cultural world of Western Christendom,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03043-9

epitomized first by the all-embracing Christian Church and second by its secular counterpart, namely the pervasive, but elusive, political order of the Holy Roman Empire. By the twelfth and thirteenth centuries, however, city republican rule, particularly in the northern half of Italy, had emerged as a new form of political order. Originally it was often modeled on trading communities and was created out of a sense of the necessity of mutual support and protection in areas exposed to incursions and with little or no protection provided by the nominal Imperial rulers.

Similarly, incipient national monarchies were starting to assert their authority vis-à-vis both pope and emperor. In this secular process the French king played a pioneering role. In particular, he had earlier than most other kings and rulers demonstrated his ability to strengthen his own position and financial basis, e.g., by confiscating lands and goods of the order of the Templars. This example was to be followed by kings across Europe in their confiscating the lands and riches of monasteries and religious orders in centuries to come.

In this sense, the Reformation and the Counterreformation meant that in Protestant and Catholic countries alike, national monarchies, normally of a composite nature (cf. Elliott, 1992), were created or reformed. This occurred on the basis of the previous dominant ideals of church, empire, and city republics, but in a form that synthesized parts that had previously been separated. Furthermore, the new national and composite monarchies almost invariably involved efforts on the part of rulers to appropriate lands and resources that had previously been controlled by the church or religious orders. Thereby they were also able to secure a fiscal basis for the new forms of political ruling, if often at a horrendous price of protracted religious civil wars and cleansings.

Under these conditions the pre-eminent political questions became that of grasping the nature and legitimacy of a normatively binding communal order and to outline the range of legitimate means for upholding and enforcing that order. Many of the early modern classical political thinkers, from Machiavelli to Jean Bodin, provide answers to these very questions. They have, however, significantly less to say about the two other sets of questions discerned above and that were to become prominent in later political thought. These were the questions of the very constitution of a community of human beings and of the principles underlying decisions about the allocations of resources or the granting or withholding of entitlements.

All this was to change with the final breakdown of the old political and cultural order in Europe in the middle of the seventeenth century. In China, even in the embattled transition from the Ming to the Ching dynasty at roughly the same time, the general linguistic and political order was preserved. In Japan a long period of internal warfare and turmoil came to an end with the establishment of one of the most effective forms of absolutist rule, namely the Tokugawa shogunate. Across the Islamic world, the three parallel empires of the Ottomans, the Safavi, and the Mughals, constituted stable political entities. In Europe, however, a new system of states took form and was promulgated in the Westphalian peace treaty of 1648, based on an explicit recognition of religious diversity and monarchical pre-eminence. It was also based on the tacit recognition that an all-encompassing imperial polity was no longer even possible as a viable political ideal and that religious diversity was not to be overcome.

Political Thought as the Constitution of a Political Community

In this unfamiliar context, there was an urgency about finding ways of granting legitimacy and meaning to the new order that emerged in the wake of the Westphalian peace treaty and the provisional end of a century and a half of bloody civil wars in Europe. Thereby a sea change occurred in political thought, namely a deep-seated shift from a concern with the enforcement of normative political order to a concern with the nature and very emergence of political community in the first place.

The concern with the constitution of political community becomes the central one in political thought from Hobbes and Pufendorf to Locke all the way to Rousseau. Within this wide range of answers there is, however, a recurring and predominant concept, namely an inquiry into the conditions for the establishment of a social contract. The existence of such a social contract was normally seen also to entail an answer to the question of which types of enforcement of the normative order constitutive of the political community are legitimate. More specifically only those types of enforcement are sanctioned that, implicitly or explicitly, follow from the terms of the social contract itself.

Political theory from Hobbes onwards is centrally preoccupied with the nature of and the consequences of a transition from an imaginary state of nature to the contractually constituted political community. Ultimately all such forms of theorizing seem to depend on a limited set of assumptions about human beings and the nature of their joining together in societies. One such set of assumptions refer to the assignment of some kind of human rights, i.e., rights that accrue to human beings irrespective of their origins and other accidental traits and characteristics. Furthermore, there is a set of assumptions that refer to the thought-experiment of society being created through a process, normally described in terms of a contract, whereby human beings agree about their association in political form.

Questions about enforcement, separate from an answer to the question of the constitution of a political order, based upon legitimately agreed upon contractual arrangements, were of subordinate and derivative importance relative to this overriding concern. The same is true of questions pertaining to the allocation of resources and the assignment of entitlements to the members and subjects of a political community. Thus such matters have to be dealt with and negotiated in accordance with the terms of those agreed upon in the original contractual arrangements.

Thus European political theory in this classical form emerged in a particular historical context both in European and world history. It also involved forms of theorizing that portrayed an imaginary contractual past as the point of constitution of polities. However, it was not in itself characterized by an effort to reflect on the history of political theory as a key component of developing such a theory. This form of reflexive consciousness was to become a key characteristic of yet another major transformation in intellectual and political history.

The Formation of Modernity and the Transition from Political Philosophy to Social Science and History

The late eighteenth and early nineteenth centuries are often described in terms of the coterminous occurrence of major transformations of both technological and economic practices and of political order. Often these transformations are captured with terms such as the industrial revolution and the political transformations inherent in the French and American revolutions. However, in this period there also occurs a major restructuring of ideas about nature and society and, more broadly, in the forms of knowledge and beliefs about the world. This intellectual transformation had deep repercussions for the emergence of new forms of political thought and reflection about the historical context of such forms of thought and for the decline of other forms of political thought.

In this period broad genres of thought about the world gradually gave way to more differentiated forms of knowledge. Slowly natural philosophy and political philosophy came to be replaced by a variety of different natural and social sciences. At the core of this transformation were epistemic shifts where ideas about biological and historical processes, about language and interpretation, about human beings and their capacities and bonds were created or reformulated. Some scholars have even spoken of this period as a second scientific revolution, where modern disciplines emerge in rudimentary form and where there is a shift in the institutional locations of scholarly and scientific activities toward new research laboratories and universities. In this process, society itself may even, to quote one scholar (Manent, 1994, pp. 80–83), be said to have been discovered in its modern form, as distinct from the political order of the prerevolutionary period, whether it had the form of an absolutist monarchy or a constitutional one. Contrary to older forms of contractual reasoning, which postulated social contract as the hypothetical medium that had created political order, the new forms of social thought were distinctly historical and could also draw on anthropological experiences of human beings and societies in different parts of the world (Fox et al., 1995).

Broadly speaking, four distinct forms of thinking about human beings, societies, and political order emerged. These new forms of reasoning and the transition from generalized moral and political philosophy to social sciences had deep repercussions for political thought.

First, there was, with roots in the political economy and moral philosophy of the Scottish Enlightenment, a view of human beings as rational and deliberative individuals and of society as a compositional collective. This also made possible a new way of thinking about political community and its legitimacy. More precisely, it provided the possibility for thinking about political order as formed through the consent of individual human beings. However it was not, as in older contractual thinking, a consent that would have ushered in a distant and hypothetical social contract but rather a consent that could be assessed and rationally evaluated in terms of its reasonableness in its present and historical context.

Second, there emerged, often enough out of the experiences of the relative inability of the French Revolution to create stable institutions, a conception of human agency as formed and constrained by structural and systemic properties and of society as an organic totality. Such a conception would in a conservative version lead to theories of the necessity to restore an organic political order. In a radical version it could, however, also usher in demands for the overthrow of unnatural and illegitimate order. In a more broadly defined liberal or republican tradition, it might and would be compatible with ideas of the type that thinkers, often inspired by Durkheim, would propound toward the end of the nineteenth century in their combat against the ideological enemies of the republic. Thus it could support the idea that modern society was not an atomistic and distorted form of human community but could relate to an organic solidarity compatible with the life of free citizens in a free republic.

Third, and often in relation to historical and linguistic thought among representative of German philosophical idealism, a conceptualization of human beings took form in terms of the linguistic-interpretative nature of human agency and of society as an historically emergent totality. In this sense, political community did not have to derive its legitimacy from dynastic tradition but from the historically grown experience of a community. Such communities in turn were constituted by human beings sharing a language and a history and where the community of shared life forms was seen as deeper, more genuine, and more real than the artificial boundaries of a minor princely state. It is easy to see that demands for national self-determination and for both popular rule and a nation-state easily flow from a conception along these lines.

Finally, in parallel to the dramatic development of forms of statistical analysis, there emerged a statistical-inductive way of representing the interactions of human beings and of society as a kind of systematized aggregate. Such views did not immediately entail a specific form of legitimate political community, but it would mean that any such community would have at its disposal infinitely more detailed knowledge of the polity and its members than even the most absolutist monarchy (cf. Brian, 1994).

Thus the great intellectual transition entailed a deep shift in the history of political thought which affected both conceptions of the nature of a political community and the nature of legitimate and illegitimate enforcement. By virtue of this it also had profound implications for conceptions of the proper distribution of entitlements. Thus it was simply no longer possible, as observed most clearly perhaps by Tocqueville (1964, [1850]), to deny demands for popular participation with reference to tradition or dynastic legitimacy. The thought of a right to the political entitlements belonging to all members of a society, that had been manifested in the proclamations of the revolutionary upheavals, could never again, despite all efforts of the Vienna Congress and the Holy Alliance, be unthought. They were to pervade the political struggles first of European and American societies throughout the nineteenth and the early twentieth centuries and eventually in the world at large.

Triumph and Crisis of Liberal Political Thought

The end of World War I marked a sea change in world history. It spelt the end of European global pre-eminence. It also meant that the transition in Western Europe, normally from forms of

constitutional monarchical rule, to parliamentary democratic rule was dramatically increased. In the Eastern half of Europe all of the four imperial political entities, the Russian, the Habsburg, the Wilhelminian, and the Ottoman, crumbled under the impact of external military defeat and internal revolutionary upheavals. However, the very triumph of liberal principles of representative democracy was coterminous with the emergence of new forms of political thought that transcended the traditions of the prewar world.

Leninist political thought, which before and during the war had been a radical version of classical Marxism, gradually came to take on the features of an official ideology of the new Soviet state. Precisely in its historical imaginary, Leninism differed from both revisionist and orthodox thought in a Marxist tradition, as epitomized by Bernstein and Kautsky respectively, of the Social Democratic mainstream of the Second International in the late nineteenth and early twentieth centuries. Thus Leninism cast its own claims to legitimacy and its right to use forms of violent enforcement, previously unthought of in late nineteenth century socialist thought, in terms of an historical account and of a projected visionary transition to a stateless society of communism.

Experiences of the mass violence of the war itself, as well as of the violent national and social struggles of the immediate postwar period, formed the environment out of which fascism emerged as a violent rejection of both Marxism and of the whole mainstream tradition of liberal political thought. Even if fascism had roots in prewar forms of radical conservative thought, it marked a form of transcendence of such traditions and indeed of the legacy of modernity itself. Thus even if fascism in power, and its radicalized form of National Socialism, embraced technological modernization, it represented a rejection of basic premises of political thought of modernity in the form it had taken since the late eighteenth century. In particular this is true of the basic presupposition of political thought of modernity of a principled equal right to participation in governance. It is also true of fascism's rejection of another basic presupposition of modernity, namely the legitimacy of a public sphere with free access for all and a principled freedom of every member of a polity to speak not only about but also to the rulers.

In a sense fascist political thought was a form of political thought that invoked history, or rather historical mythology. However, it was not in itself characterized by historical reflection. In Germany, the challenge of fascism to the political order of the Weimar republic was manifested in a range of debates, one of the most important of which concerned the nature of legal order and of the state itself. It was in this debate that the contesting positions of the radical and pro-Nazi decisionism of Carl Schmitt was confronted by the legal positivism of Hans Kelsen and the complex and sophisticated thought of Hermann Heller.

The outlines of a radical rethinking of the history of Western philosophical and political thought can be discerned in the elective affinity between fascism and some forms of philosophical thought, in particular that of Heidegger of the late 1920s and early 1930s. However, such a program was never elaborated or extended, nor was the decisive response and resistance to it on the part of a thinker such as Ernst Cassirer. Instead the military defeat of fascism in World War II was seen to entail the definitive demise of features of political thought characteristic of fascism.

In the French context, the response to the challenges of fascism was to be found in several quarters. These would range, in political terms, from Marxism to radical Catholic political thought, and in scholarly terms, from sociology in the tradition of Durkheim to the profound renewal of historical studies of the Annales School. In the period after World War II, the French intellectual scene may have been the most important one in Europe in terms of a renewal of political thought. Thus it would comprise the nexus of contributions made by scholars elaborating a Marxian philosophical existentialist position, most importantly of course Sartre, but also thinkers such as Claude Lefort, who, starting out from such a position came to question the core of Leninist political thought. It would also comprise some of the most articulated liberal political thought as epitomized by Raymond Aron.

In the interwar years, the new challenges to liberal political thought had already given rise to a profound renewal of political thought in historical context. These were the years when new standard histories of political thought were being written. The most prominent example in the Anglo-Saxon world might have been a book that was to become a classic for generations, namely George Sabine's (1937) majestic volume *A History of Political Theory*. Refugees from continental Europe made key contributions to this debate. A classical example is the analysis of the meaning of democracy in historical context that was articulated by Joseph Schumpeter (1943) in *Capitalism, Socialism, and Democracy*. Most importantly, perhaps, Karl Popper transcended the bounds of philosophy of science and wrote one of the most quoted works in political thought during the twentieth century in his two-volume opus on *The Open Society and Its Enemies* (Popper, 1966, [1945]). This was, of course, a work that was pre-eminently characterized by the links between historical analysis and political philosophy of immediate and contemporary relevance.

In parallel, leading representatives of Scandinavian political and legal science made some pathbreaking contributions both to an understanding of fascism and of the nature of democracy. In this respect the names of Herbert Tingsten and Alf Ross stand out, particularly with Tingsten's pioneering studies of fascism and his and Ross's contributions to a political theory of democracy.

One prominent characteristic of antiliberal political thought of the first half of the twentieth century was its emphasis on the right of the polity to resort to enforcement and violence against the enemies of the polity without being bound by any other constraints than those of pure convenience. Thus the constitutive boundary between members and enemies of the political community, between those chosen to fulfill the destiny of that community and those deemed to stand in the way and worthy of being removed from community, and ultimately from life, became the most crucial one. The political community itself was seen as constituted in terms of a historical account, whether of the struggle of a class for its liberation against oppression or of a people for its legitimate sphere of life and domination. Resistance to such types of political thought of a historicist nature formed the core of the argument of Popper's political philosophy. It also formed the focus for

a range of contributions criticizing totalitarian political thought. Among the main contributors to this critique were thinkers as different as Jacob L. Talmon, Hannah Arendt, and Claude Lefort.

Renewal and Critique in Political Thought

The history of political thought in the first part of the latter half of the twentieth century is characterized by three parallel developments. First, political thought in this period cannot but reflect the deep tensions in a world with two superpowers in a state of cold war. At the same time large parts of the Third World were emerging out of the experiences of a colonial past and seeking a place in this new world of fundamental tensions. One manifestation of this historical context, was the absolute absence of publications in the tradition of liberal political thought in the countries under Soviet dominance, but also the relative absence of Marxist political thought at many universities in the English-speaking world. Another indirect consequence was a persistent interest in exploring the empirical basis of liberal democracy. In this sense, the contributions by scholars such as Robert Dahl and some of his colleagues at Yale university, not least Charles Lindblom, stand out as exemplary. Second, a classical mainstream tradition of historically orientated political philosophy made significant advances. Isaiah Berlin and Judith Shklar are pre-eminent representatives of this type of scholarship, and the works of Charles Taylor and Norberto Bobbio should also be included here. Third, however, philosophical and theoretical contributions were made that were to reshape the history of late twentieth century political thought. I shall highlight some of these contributions and their consequences in terms of two of the major conceptualizations of human agency and of society that were discerned in the section above about the rise of the social sciences at the turn of the eighteenth century.

In a rationalistic-deliberative tradition, a landmark was established by the publication of Kenneth Arrow's (1951) *Social Choice and Individual Values*. A few years later, economic theorizing would enter political science at large with Anthony Downs's (1957) book *An Economic Theory of Democracy*, to be followed in the early 1960s by a range of books applying game theory and social choice theory to political phenomena. (Incidentally, as testified by Gabriel Almond (1990, p.117) the institutional role of the Center for Advanced Study in the Behavioral Sciences at Stanford was a crucial one for some of the interactions involving Arrow, Dahl, and others. These interactions were of immediate importance to the very publication of Downs's book but also more generally to the breakthrough of rationalistic forms of analysis).

A few decades later, what had once appeared as an interesting but rather marginal concern of some specialized political theorists had evolved into a broad tradition of rational choice analysis with pervasive influence on both the theory and practice of political thought, particularly in North America. Society as a compositional collective was described not just as an analytically convenient metaphor but as a representation of societal order and with consequential claims concerning the nature of legitimate political action. One thrust of theorizing in this tradition was to demonstrate the limitations, or even the impossibility, of delimiting an unambiguous common good, whether arrived at with the help of a social welfare function or of a majority decision. It is in this context that John Rawls's (1971) *A Theory of Justice* appeared as a pathbreaking book. Drawing on an individualistic and contractual form of reasoning, succinctly criticised by several scholars, most notably perhaps Michael Sandel, Rawls was able to reintroduce discussions of justice and just distributions and allocations into the core of political philosophy. Even after decades of discussions and critique, both Arrow's and Rawls's contribution retain their stature. However, both of them signal a rupture with historical and contextual reasoning rather than the opposite.

In the broad tradition of linguistic-interpretative conceptions of human action and of society as a form of emergent totality in historical context, important new developments also occurred. Thus contributions by continental European phenomenological and hermeneutic philosophers in the 1950s and 1960s came to merge with influences from Anglo-Saxon linguistic philosophy in the tradition of Wittgenstein and Austin. Three forms of such thought, in particular, emerged and have exerted a deep influence on the ways of studying the history of political thought.

In 1959, Reinhart Koselleck (1988, [1959]), drawing on a tradition of hermeneutic and historical scholarship, published a book on critique and crisis. This book had the deep transformation of intellectual and political order at the turn of the eighteenth century as its focus but also contained the core of a research program on the history of key concepts of society and political order in a long-term perspective. This program was realized through the publication during the following decades of a set of nine massive volumes tracing the history of a limited number of such concepts, primarily in continental Europe.

Roughly at the same time, Jürgen Habermas elaborated another research program, drawing on the joint traditions of critical Marxist thought, hermeneutics, and speech act theory. In 1962 Habermas published a volume that had an analogous empirical focus as that of Koselleck (Habermas, 1989). Thus it was a reinterpretation of the emergence of a new type of public sphere in the late eighteenth century. Habermas's subsequent long-term program has consistently linked these different traditions and may in one sense be seen as a form of historical positioning but also a radical generalization of the philosophical insights of linguistic philosophy and speech act theory.

This later tradition also inspired Quentin Skinner's (1978) two volume major opus *The Foundations of Modern Political Thought* (a work, incidentally, written largely at the Institute for Advanced Study at Princeton). Skinner came to be the major representative of a new school, often identified with his – and John Pocock's old – university, namely Cambridge. It involved the setting of new and significantly more rigorous standards for the writing of the history of political thought, particularly in its demand that the linguistic and intellectual context of the actual writing of major works be carefully brought to the fore of analysis. After decades of discussions, there can be little doubt that intellectual history has made advances in this period, inspired by the works of Skinner and several of his colleagues, that still by no means have been fully explored. At the same

time, it is also clear that these works still leave room for a more extensive inquiry into the relationship between long-term institutional and intellectual change.

Finally, links between political thought and political agency are prominent in studies of mechanisms of inclusion and exclusion and on the granting and withholding of entitlements for human beings. Gender studies has clearly entailed a renaissance of the writing of the history of political thought with pioneering contributions by Carole Pateman and Seyla Benhabib, just to mention two of the most distinguished scholars on the late twentieth century.

Historically orientated scholarship has in recent years seemed to open up the possibility for situating political thought in a much more encompassing context than has hitherto been customary. Not least, scholars writing in countries outside of the North Atlantic and West European context seem now to be about to help bring about a more truly global effort to rethink the history of political thought. That would also, almost inevitably, contribute to a transcendence of some of the most severe limitations of contemporary political thought, in particular the following ones:

> The relative inability of political thought in the rationalistic tradition to transcend a theory of agency that is manifestly impoverished vis-à-vis available historical research but also vis-à-vis demands that social and political thought itself cannot but make concerning a theory of agency.
>
> (cf. Joas, 1996, 2000)

> The relative inability of the so-called communitarian critics of this tradition to supply a sustained historical account of their preferred community and to escape a tendency of entering into circular justifications of those very societies which they themselves happened to be located or identified with.
>
> The relative inability of research in the traditions of conceptual history and linguistic contextualism to contribute to an understanding of the institutional formation of political order in a long-term and also extra-European perspective.

In order to be able to advance beyond these limitations, it seems that political thought must become significantly more prepared to engage in studies of long-term processes of intellectual and institutional transformations. This will in all likelihood entail efforts to invigorate historical social science of a type that was characteristic of the classics of social science, not least Weber (cf. Schluchter, 1996). It would then also stimulate culturally and contextually sensitive social science of a type that has been advocated most ambitiously and consistently by scholars across a range of the social and historical sciences and with S. N. Eisenstadt (1995) as one of its most prominent representatives. The history of political thought in the last three decades of the twentieth century involved impressive advances. At the turn of the millennium, however, the need for historically and comparatively orientated research programs able to transcend the limitations of contemporary political thought also stand out as possibly more urgent than at any time since the emergence of social science itself in the end of the eighteenth century.

Abstract

The study of past ideas and writings concerning politics has been undertaken not just by historians, but by scholars from a variety of different disciplinary perspectives. This article focuses primarily on historical approaches to the study of past thinking about politics. In particular, three approaches that have been especially influential in the late twentieth and early twenty-first centuries are explored in detail: the Straussian approach initiated by Leo Strauss; the Cambridge School interpretation that was developed by J.G.A. Pocock and Quentin Skinner; and Begriffsgeschichte or Conceptual History that was pioneered by Otto Brunner, Werner Conze, and Reinhart Koselleck.

Definition

The history of political thought is a field of study which explores past ideas and writings concerning politics and can cover a whole range of issues including democracy, freedom, constitutionalism, and political obligation. As the label suggests, it is technically a subdiscipline of history and consequently, many practitioners emphasize the commonality in terms of subject matter, approach, and methodological techniques with other branches of history. However, the history of political thought also shares much in common with other disciplines and subdisciplines including philosophy (particularly ethics and political philosophy); politics, political science, and political theory; intellectual history, cultural history, and even literary history. Moreover, some of those who have made important contributions to the history of political thought are more comfortable describing themselves as political scientists or political philosophers than historians of political thought.

While scholars from different disciplines can and do work together and build on each other's findings, they have sometimes approached the study of past political thought with rather different purposes in mind. For example, some of those concerned with the study of politics or government have presented their own ideas against the background of accounts by previous writers, stretching back to Plato and beyond. Yet, in these cases, the study of these texts and ideas is viewed from the perspective of present concerns. The same has also been true of philosophers interested in political and ethical issues. Such scholars tend to focus on a canon of key texts or figures who are effectively seen as exploring the same issues and as engaging in dialogue with one another. In reaction to this, others in these fields have challenged the relevance of past discussions of political issues in favor of an empirical social science approach that focuses on how politics operates today or a philosophical analysis of political concepts exploring the grammar underpinning their current use. Set against these various trends (as well as against those historians who downplay the relevance of political thought, or even ideas more generally, to historical enquiry) is the orientation of those historians who have been interested in the history of political thought.

Even among those who consciously study the history of political thought there is no single approach to the subject. Rather a number of different methodologies have been developed. Consequently, the remainder of this article will focus on three approaches that have proved particularly dominant over the past 50 years and remain so today: the Straussian approach that takes its lead from the work of Leo Strauss; that of the Cambridge School, the leading figures of which are J.G.A. Pocock and Quentin Skinner; and Begriffsgeschichte or Conceptual History that was pioneered by the German scholars Otto Brunner, Werner Conze, and Reinhart Koselleck.

Approaches

Leo Strauss and the Straussians

Though difficult to comprehend in the current climate, in the early to mid-twentieth century the history of political thought was widely perceived to be an obsolete field, having been supplanted by a scientific approach to politics more typical of the social sciences. The German-born American political philosopher Leo Strauss (1899–1973) analyzed this situation; offered a robust critique of the 'new political science'; and so helped to bring about the revival of the discipline (Smith, 2009: 2).

The major starting point of Strauss's thought was the idea that the modern world had reached crisis point: "The crisis of modernity reveals itself in the fact, or consists in the fact, that modern western man no longer knows what he wants – that he no longer believes that he can know what is good and bad, what is right and wrong" (Strauss, 1975: 81). And, of course, this has important implications for questions such as what sort of government is desirable or when opposition to rulers is legitimate. In an attempt to understand this crisis Strauss drew a sharp distinction between the ancients and the moderns, inverting the outcome of the early eighteenth-century 'querelle des anciens et des modernes' by asserting the superiority of the former over the latter. On Strauss's analysis it was Niccolò Machiavelli and Thomas Hobbes who signaled the beginning of the modern era and initiated the first of three waves of modern thought (Strauss, 1975: 81).

Machiavelli was among the first to challenge the belief in a set of fundamental and eternal values governing human morality and politics, as well as the notion that there is a single ultimate form of human perfection. He thus shifted the focus of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62163-3

political thought from how humans ought to live (the ideal) to how they actually live (the pragmatic or practical). In doing so Machiavelli was accused by Strauss of opening the door to the relativism and nihilism that characterized the twentieth century, and which arguably is still with us today. At the same time Machiavelli introduced the idea that rather than having simply to submit to chance, as ancient thinkers had believed, human beings actually had the capability to shape and even control fortune, if they were sufficiently cunning. This idea was then developed in the midst of the scientific revolution of the sixteenth and seventeenth centuries, becoming manifest in the Enlightenment belief that through science and technology human power could be used to conquer and control nature and to reform society. The application of scientific methods not just to the natural world, but also to human nature and society posed a particular problem for Strauss since science deals in facts not value judgments, whereas the human and social sciences, such as political philosophy, depend upon deep-seated value judgments that must simply be accepted rather than being rationally validated. Ultimately, Strauss was concerned at the idea, prevalent in the social sciences at the time and epitomized by Max Weber, that a scientific approach could supplant the ancient role of philosophy. Thus, the ancients were superior, in his eyes, because their philosophers (though not necessarily the people more generally) appealed to eternal values and had a clear sense of what was just, virtuous, and good. This was true not only of the classical philosophy of Plato and Aristotle, but also of the account offered in the Bible: in this "crucial respect there is agreement between classical philosophy and the Bible, between Athens and Jerusalem, despite the profound difference and even antagonism between Athens and Jerusalem" (Strauss, 1975: 86).

In his analysis of western political thought Strauss sought to counter this loss of knowledge by both uncovering the innovations of the moderns (including positivism and historicism) and reemphasizing and reinvigorating the eternal concepts and values of the ancients. This also had an impact on the way in which he approached the history of political thought and his methodology. In studying the ancients Strauss was primarily concerned with their understanding and appreciation of fundamental values. When he came to the moderns he focused on their undermining of these values and the consequences that ensued. His works thus read as though the canon of great thinkers were essentially engaged in discussion with each other and the focus is almost exclusively on their development and transformation of the field of political philosophy. His methodology therefore focused almost entirely on the texts. He paid very little attention to the historical and intellectual contexts in which they were written, firmly rejecting the idea that an appreciation of these is necessary in order to fully understand the ideas themselves.

In challenging the path taken by modern thinkers, Strauss drew inspiration from the approach to philosophy that had been taken by Arabic thinkers during the medieval period, in particular Abu Nasr Alfarabi (*c*.870–950). These thinkers offered, so Strauss contended, a deeper interpretation of the ideas of ancient philosophers such as Plato and Aristotle than was common in parallel western accounts, with the Arabic writers retaining a belief in certain eternal ethical and political concepts. Strauss also drew from these thinkers his controversial concept of esotericism. It was based on the idea that most political thinkers in the past had to conceal their deepest ideas to avoid persecution. This called for a reinterpretation of the canon and a new emphasis on 'careful reading' to uncover the hidden meanings of the great thinkers of the past.

Though Strauss himself died in 1973, his approach has survived and continues to be influential, particularly in the United States. Not all Straussians agree with each other and there are particular distinctions between the East and West Coast groups. One topic that has received emphasis from Straussians in recent years (partly in response to its emphasis among historians of political thought who adopt the rival Cambridge School approach) is republicanism. Paul Rahe offered a fundamentally Straussian account of the history of republican thought in his enormous book *Republics Ancient and Modern*, which appeared in 1992. As its title suggests, it was an attempt to underline the fundamental caesura introduced by Machiavelli. Crucial here was the shift away from seeing civic virtue as inherently good and valuable toward a much more instrumental understanding of it as a means of achieving freedom and individuality. In his more recent book, *Against Throne and Altar*, which focuses more closely on the period of the English Revolution, Rahe developed his account of the emergence of modern republicanism more fully while also paying closer attention to the legacy and influence of Arabic authors including Alfarabi and his followers (Rahe, 2008). This Straussian interpretation of republicanism has been further explored by other scholars including Thomas Pangle and Vicki Sullivan.

The Cambridge School

The series of approaches known collectively as the 'Cambridge School' were devised, at least in part, as a response by historians to Strauss's political philosophy and other philosophical approaches. The leading figures of this school, J.G.A. Pocock and Quentin Skinner, were motivated by similar concerns and had shared aspirations, but each developed his own particular approach. This school derives its name from the fact that it was at Cambridge that Pocock and Skinner first developed their methodological ideas and that institution also housed other pioneers and practitioners of the approach, most notably John Dunn, Peter Laslett, and Gareth Stedman Jones. Before exploring the particular approaches of Pocock and Skinner in detail it is worth focusing on the concerns that prompted their methodological work and the common features that their investigations share.

Essentially, the approach of the Cambridge School was designed to cut a middle way between history and philosophy. Pocock, in particular, was concerned that the study of past political thought had tended to be dominated by philosophers who lacked a proper historical training. Consequently such philosophers were less concerned by what past authors intended by their claims and more interested in what "he in his present can make it mean: what he can do with it for purposes of his own, which may or may not – and therefore do not have to – coincide with those of the author" (Pocock, 1971: 7).

A further consequence of this philosophical focus was the tendency to understand the history of political thought in terms of a canon of greater thinkers and texts. As Pocock

explained: "Alone among the major branches of historical study in the middle twentieth century, the history of political thought was treated as the study of a traditional canon" (Pocock, 1971: 5). Skinner too was concerned by this tendency, directing his criticism more specifically at the Straussians and their apparent assumption that the great political thinkers of the past had effectively been engaged in a dialogue with each other, rather than being largely inspired by and engaged with the troubles, debates, and thinkers of their own time. Thus, members of the Cambridge School were keen to re-establish the historical dimension to the study of political thought and to construct it as a firmly grounded historical discipline.

At the same time advocates of the Cambridge School also expressed their discontent with a marked tendency among historians to downplay or even dismiss ideas completely. This was not only a feature of high political and Namierite interpretations that saw ideas as little more than a means of rationalizing what were in reality selfish political interests, but also of the Marxist approach. Here political thought tended to be viewed as mere 'idealism,' with ideas simply reflecting more fundamental social and economic factors. Indeed even where Marxist-inspired scholars did treat ideas more seriously, as with C.B. Macpherson in his influential, but controversial work, *The Political Theory of Possessive Individualism*, they tended still to be portrayed as superficial representations of deeper social phenomena (Pocock, 1971: 10 and 37).

Ironically, given the concerns about philosophical approaches to the study of the history of political thought, the methodologies that Pocock and Skinner developed to chart their middle course were themselves grounded in philosophy, more specifically the linguistic philosophy of the 1950s. "What seemed to many, about 1956, the subversion of political philosophy by linguistic analysis helped to liberate the history of political thought by converting it from a history of systematization ('philosophy' in an old sense) into one of linguistic use and sophistication ('philosophy' in a new)" (Pocock, 1971: 11–12). Thus members of the Cambridge School drew on several philosophical ideas and theories. These included Ludwig Wittgenstein's explorations of the diverse language games in terms of which human beings make sense of the world and J.L. Austin's notion of speech acts. Also of influence was Thomas Kuhn's treatment of the history of science in terms of paradigms and paradigmatic shifts.

Pocock's approach sought to move the focus away from particular thinkers or texts by adopting political languages as the key unit of analysis and examining the ways in which those languages were developed, adapted, and even subverted over time. What he meant by political language, he explained, was the idioms, rhetorics, specialized vocabularies, and grammars – the modes of discourse or ways of talking about politics that developed at particular points in the past (Pocock, 1971: 21). It was the task of the historian of political thought, he insisted, to learn these languages by reading many texts in order to be in a position to detect not only uses of them, but also developments, refutations, and subversions. In his own work, Pocock has focused on what he saw as a number of particularly significant early-modern political languages including the common law, civic humanism (or republicanism), and political economy, but his approach has also inspired the in-depth study of other languages, including natural law.

Though undoubtedly influenced by Pocock's emphasis on languages, Skinner has adopted a slightly different approach by emphasizing the need for historians of political thought to address the authorial intention or the 'illocutionary force' of particular speech acts. In other words, Skinner insisted that an historian of political thought should seek to uncover exactly what a particular thinker or writer intended or meant by a particular statement or work; how it fitted within, altered, or subverted the conventional understandings of the time; and what (s)he was seeking to achieve by it.

While both of these approaches require the close reading of particular texts in order to uncover their precise meaning, they also depend on a deep understanding of the immediate context in which the author was writing. Moreover, this includes not only the historical or political context, the particular events or issues of the time that stimulated the author into producing the ideas or works that (s)he did, but also the intellectual context: the other works on which the author drew or against which (s)he was arguing and the debates in which (s)he was engaged. This emphasis is perhaps best illustrated in *The Foundations of Modern Political Thought*, which Skinner published in 1978. The aim of these two volumes (covering the Renaissance and the Reformation, respectively) was to provide the background or context in which some of the great works in the history of political thought had been written. Unlike normal textbooks in the history of political thought these did not simply provide a summary of the key works themselves, rather they were designed to be read in conjunction with the texts and would help the reader to situate the works in their appropriate contexts. More recently, this approach has been further supported by Cambridge University Press through two series devoted to the history of political thought. The first, *Cambridge Texts in the History of Political Thought* (colloquially known as the blue texts series on account of the distinctive covers), offers cheap and accessible editions not only of the great canonical works, but also of other works of interest and distinction from the ancient world right up to the present. Each volume also includes a scholarly introduction designed to outline the context in which the work was produced. Secondly, *Ideas in Context*, a collection of scholarly monographs and edited collections relating to various aspects of the field.

As always with advocates of new and influential methodologies, the Cambridge School has not escaped criticism. Some have questioned the universalist claims that have been made for an approach that has centered largely on political texts produced between around 1450 and 1800. Others, more specifically, have derided the elitism inherent in the approach and have criticized the alleged absence of any real exploration of social background or institutional structure or indeed of the reception of texts and ideas. Still others have questioned whether Skinner, in particular, really applied his own theories in practice. Despite placing emphasis on intellectual context and lesser known ideologies and thinkers, his own work has continued to center on key figures such as Machiavelli and Hobbes. At the same time, though preaching a properly historical approach, some have argued that his work is teleological in its focus on the emergence of modern concepts such as the state. Despite these criticisms, over the last 40 years, the Cambridge School approach has become the dominant method for pursuing the history of political thought in Britain

and has also proved influential abroad, although on the continent it has had to contend with a distinctive and distinguished alternative in the form of Conceptual History.

Conceptual History

In Continental Europe, and particularly in a German and Dutch context, a different approach to intellectual history and the history of political thought has been pursued by advocates of Begriffsgeschichte or Conceptual History. The origins of this approach are similar in a number of respects to those of the Cambridge School. Like Pocock and Skinner, advocates of Begriffsgeschichte were trained historically and consequently their approach is firmly grounded in historical methodology. Once again, it is in part a response to the Straussians. It also shares with the Cambridge School (and especially Pocock) its emphasis on language (particularly political language) and the ways in which meanings and usages change over time. However, in contrast to Pocock and Skinner, advocates of Begriffsgeschichte focus their attention on key concepts and treat these – rather than texts, thinkers, or languages – as central to their analysis.

The founding work of this movement was the Geschichtliche Grundbegriffe (GG), a huge historical dictionary or encyclopedia of concepts, which was first announced in 1967 and the first volume of which appeared 5 years later. There were three key figures involved in this project. First, Otto Brunner, whose background was in medieval philology, but who had anticipated many of the ideas of Begriffsgeschichte in his influential book Land und Herrschaft (*Land and Lordship*) of 1939. Secondly, Werner Conze, a social historian and a pioneer of labor history in Germany (Van Horn Melton, 1996: 33). Thirdly, Reinhart Koselleck, who is perhaps best thought of as an intellectual historian and is the only one to have seen the project through from beginning to end. It was Koselleck who apparently came up with the idea of producing a dictionary of concepts while working for Conze (Tribe, 1989: 180). But it was also Koselleck who completed the project after the death of Brunner in 1982 and Conze in 1986. The initial plans for the project were relatively limited. A single volume focused on German concepts was envisaged. However, by the time the final volume appeared in 1997, the work consisted of eight volumes, comprising 120 entries and more than 7000 pages.

The breadth of interests among the editors is reflected in the GG and in Begriffsgeschichte more generally. The focus is not simply on political thought, narrowly defined, there is also a strong social history dimension and a real attempt to integrate the two. From the outset, Koselleck was keen to take full account of sociopolitical experience rather than simply focusing on ideas and to emphasize the interrelationship between them (Tribe, 1989: 181; Koselleck, 1985: 73–91). As he explained: "Without common concepts there is no society, and above all, no political field of action. Conversely, our concepts are founded in politicosocial systems that are far more complex than would be indicated by treating them simply as linguistic communities organized around specific key concepts" (Koselleck, 1985: 74). Moreover the emphasis is on exploring the debates surrounding the meaning of particular concepts and uncovering the relationship between conceptual change and more concrete social structural transformations (Richter, 1990: 41).

Another key difference between the Cambridge School and German advocates of Begriffsgeschichte is that members of the former have tended to focus their attention on the period between the fifteenth and eighteenth centuries, whereas the latter were focused more narrowly on the period between the mid-eighteenth and mid-nineteenth centuries. Brunner had already presented the nineteenth century as constituting a fundamental break with the past in his earlier work and he saw conceptual history as a means of bridging that gulf between past and present (Van Horn Melton, 1996: 22). However, it was Koselleck who dubbed this period the Sattelzeit or saddle period, and defined it as an era of rapid political and social change during which a number of distinctively modern political and social concepts were said to have emerged. As Koselleck himself explained, the aim was: "to investigate the dissolution of the old world and the emergence of the modern world through the history of its conceptual comprehension" (Tribe, 1989: 183). In the GG a distinction is drawn between three types of concepts (Koselleck, 1985: 82). First, those long in use, in particular terms that had been applied in antiquity and are still current in the modern world. Secondly, those concepts whose meaning was completely transformed during the shift to modernity (for example, state/estate). Thirdly, neologisms which were invented generally during the Sattelzeit (such as communism or fascism). The project also highlighted four processes that commonly affected basic political and social concepts in the German-speaking world between 1750 and 1850. First, Verzeitlichung, which refers to the tendency: "to insert modern political and social concepts into one or another philosophy or horizon of history set out teleologically in terms of periods, phases, or stages of development" (Richter, 1996: 12). Secondly, Demokratisierung or the democratization of political and social vocabularies that had previously been confined to an elite. Thirdly, Ideologiesierbarkeit or the incorporation of concepts into ideologies. Finally Politisierung or the politicization of concepts and their use for political purposes.

While initially developed in relation to the German-speaking world, Begriffsgeschichte has subsequently been applied to other European languages. Rolf Reichardt and E. Schmidt adopted a similar approach to French history in their Handbuch polititisch-sozialer Grundbegriffe in Frankreich 1680–1820 (*A Handbook of Political and Social Concepts in France*, 1680–1820), which appeared in 1985. Reichardt has also continued to pursue this approach in his more recent work, which has often set the exploration and interpretation of visual images alongside more traditional written texts.

In the 1990s, a group of Dutch scholars were also attracted to this approach and several of them established a research project in Dutch conceptual history. The initial project focused on three key concepts that were seen to be important in a Dutch context: Liberty, Fatherland, and Citizenship. Three interdisciplinary research groups were set up to explore each of the concepts in a Dutch setting. Since then the project has expanded in several ways. In the first place, the group has begun to work on additional concepts, including honor, gender, state/estate, and modernity. The ambitions are perhaps less grand (in this sense at least) than the GG, with talk of up to 15 concepts in total. However, attempts have also been made to develop a more comparative approach. A series of workshops has already been held in which the use of the three

initial concepts in a Dutch context was contrasted and compared with the ways in which those same concepts developed in British, French, and German settings. A comparative approach was also offered in a volume that was produced by the group in 1998 and was entitled *History of Concepts: Comparative Perspectives* (Hampsher-Monk and Tilmans, 1998). Interestingly, the Dutch scholars set out with the specific intention of exploring the distinctiveness of the Dutch experience. This led to a greater focus on the seventeenth century (as a particular high point in Dutch history) and the expectation that the Sattelzeit would be of less significance in a Dutch context. However, the preliminary findings suggest that this was not the case and that in Dutch, just as in German, it was the period between 1750 and 1850 that witnessed the emergence of the modern conceptual world.

Similar projects have also been proposed focusing on other linguistic areas. In his contribution to the American conference to celebrate the completion of the GG, Melvin Richter spoke of the possibility of a Hungarian project and referred to an additional initiative relating to keywords of the Chinese Revolution from 1911 to the present (Richter, 1996: 19). More recently British and French scholars have become interested in exploring keywords or concepts and several projects based around this idea are currently taking shape.

Although conceptual history appears to be on the rise, there are still problems and drawbacks with the approach pioneered by the GG. In particular the alphabetical organization of that work presents obstacles to its usage, hindering – for example – attempts to use it to construct vocabularies or languages that were dominant at particular times. Interestingly the editors had originally hoped to implement a more complex organization that would have rendered these kinds of connections easier to make, but the complexities involved in doing so pushed them toward the lexicon format. One of the central tenets of Richter's attempts to integrate the Cambridge School and Begriffsgeschichte approach has been to stress what the latter could learn from the focus on languages or ideologies that is characteristic of the work of the Cambridge scholars. Criticism has also concerned the particular periodization adopted by the GG, and especially the emphasis on the period 1750–1850. Yet, given the tentative findings of the Dutch project it may be that this focus is more justified than some have thought.

Conclusion

As this overview has demonstrated, there are different ways of approaching and studying the history of political thought. These approaches each have their own strengths and weaknesses, and their practitioners might indeed learn from each other as Richter suggests. While there is no single dominant approach, what can be said with confidence is that the fortunes of the field have been transformed over the last century. Having been deemed obsolete in the early twentieth century it would seem that the history of political thought is alive and well at the beginning of the twenty-first.

Political Tolerance

Sandra T Marquart-Pyatt, Michigan State University, East Lansing, MI, USA

Abstract

Political tolerance is essential to vibrant, healthy democracies. It involves taking key democratic principles like support for civil liberties and political rights and applying them in practice to disliked groups. Scholars have tracked public opinion on tolerance for more than 60 years using group-specific and content-controlled measures. Recent works have expanded the focus from the United States to other established democracies and to nascent democratic regimes. These studies reveal intolerance to be widespread around the world and strive to understand why this is the case.

Introduction

Political tolerance, defined as the willingness to grant political rights to disliked groups, is central to studies of democratic values given its links with civil liberties and political freedoms. For more than six decades, scholars have tracked public opinion on political tolerance given its role in supporting democratic values and political rights like freedoms of speech and association and the right to vote, demonstrate publicly, and hold an elected political office. Taken as a whole, these studies have yielded many insights. Of these, perhaps most significant is that establishing and maintaining tolerant publics, even in long-standing democratic nations, remains a challenge. Nontrivial gaps between tolerance in principle and in practice remain in both established and nascent democracies (Marquart-Pyatt and Paxton, 2007). While in some contexts intolerance toward specific groups has fluctuated and may have even attenuated, it is also possible in other contexts that levels of tolerance have remained the same or perhaps even increased (Gibson, 2008, 2013; Shafer and Shaw, 2009; Sullivan and Hendriks, 2009). In addition, in the United States a shift in attitudes toward granting the government authority to suspend civil liberties such as in the aftermath of 9/11 has had a profound influence on this work (Davis, 2007; Sullivan and Hendriks, 2009). Although a growing number of studies attest to the importance of investigating tolerance worldwide, research reveals it to be contextually grounded as well as potentially developing at uneven rates globally, leading to complexities with regard to how it is realized locally, nationally, and globally.

Since the seminal work on political tolerance in the United States by Samuel Stouffer (1955) describing how the American public viewed the civil liberties of communists during the McCarthy era, research has investigated different ways of measuring tolerance, broadened in geographic scope to national and cross-national work, and considered a number of theoretical frameworks. Studies have employed different measures of political tolerance, including fixed-group and content-controlled measures, for a number of different social, political, and ethnic groups. Much of this research has been country-specific, focusing on tolerance in the United States (Gibson, 2008, 2013; Sullivan and Hendriks, 2009; Sullivan and Transue, 1999). Research on political tolerance in the American public has examined tolerance over time toward left-wing political groups like communists and socialists, atheists, religious groups like Muslims, and right-wing racists (Sullivan and Hendriks, 2009). As described in this article, research has also explored tolerance in other established democracies like Australia, Britain, and Israel, as well as in newer democracies like Poland, the former Soviet Union, and South Africa. Few of these studies attempt to compare across new and established democracies, however, and even fewer attempt comparisons across a substantial number of countries. A handful of recent works examine political tolerance across more than two dozen countries. A variety of explanations have been used to characterize individual-level variation in tolerance including democratic norms (Sullivan et al., 1982, 1985), democratic learning and protest (Guerin et al., 2004; Marquart-Pyatt and Paxton, 2007; Peffley and Rohrschneider, 2003), and threat perception (Sullivan et al., 1982, 1985). An emerging line of inquiry seeks to include macro-level frameworks like democratic learning (Peffley and Rohrschneider, 2003).

Political tolerance entails the extension of political rights to groups with opposing or disliked views and is a pivotal democratic value essential for democratic functioning and survival. Political tolerance involves taking key democratic principles like support for civil liberties and minority rights and applying them in practice to disliked groups. Healthy democracies require citizens to put up with or tolerate the views and political participation of other groups, even those groups whose views they might oppose or whose participation they may perceive as threatening (Almond and Verba, 1963; Sullivan and Transue, 1999). Political intolerance targets the political freedoms of particular groups and ideologies through restrictions on civil liberties like freedom of expression and association. Tolerance is especially important in nascent, unconsolidated democracies where intolerance may cause instability in providing transitions from one regime to another as groups resist ceding power to rivals or try to institutionalize restrictions on civil liberties for particular groups (Guerin et al., 2004). Tolerance is also salient in established democracies given its crucial role in solidifying a broad array of civil liberties and political rights for a wide range of groups.

In this article, I provide an overview of published research on the topic of political tolerance that covers three areas: (1) measures of political tolerance in the literature; (2) national, international, and comparative research grouped into single country case studies, comparative small sample (N) and large N

works; and (3) major explanatory frameworks and variables investigated. Special emphasis is placed on work published in the last two decades to facilitate discussion of the road ahead that includes a brief overview of existing datasets available for secondary analysis of political tolerance across nations and contexts and conceptual issues that remain, laying a foundation on which future theoretical and empirical work can build.

Measuring Political Tolerance

The extant literature employs a number of different measures of political tolerance. Although conceptually related, political tolerance is neither synonymous with civil liberties nor is it necessarily linked with social or ethnic tolerance (see Gibson, 2008). At least three approaches to measuring tolerance can be gleaned from this scholarship. Two are vital to distinguish given their long-standing influence on tolerance studies: group-specific or fixed-group and content-controlled measures. A third is also important given how it engages policies related specifically to restrictions on civil liberties with corresponding implications for democratic theory. In the following, each is described in turn, although the bulk of attention is devoted to the first two measures.

One measurement strategy in tolerance research is a group-specific or fixed-group approach. Group-specific tolerance research asks questions about particular groups such as communists, socialists, and atheists (Stouffer, 1955; Nunn et al., 1978). These items are routinely gathered in the General Social Survey (GSS) (Smith et al., 2013). The GSS is a nationally representative sample of the US public, conducted since 1972, containing information on demographic, attitudinal, and behavioral questions on a range of social issues. Regarded as an excellent source of societal trend data, the GSS has included questions about a few groups in many years and some in specific years including, for instance, communists, socialists, militarists, atheists, feminists, gays and lesbians, and immigrants.

Studies using fixed-group measures of tolerance over time reveal that some groups included in this set of survey items have become more socially accepted while others have not necessarily been recipients of more welcoming attitudes. A recent trend article using the GSS illustrates broad patterns among survey respondents of mildly increasing tolerance toward people who differ from them, especially for gay and lesbian individuals (Shafer and Shaw, 2009). Rather than being illustrative of a broad shift, however, Shafer and Shaw (2009) suggest this may indicate that other groups in this time frame from the early 1990s to 2007 may have moved into the category of least-liked. This confirms the work of Sullivan et al. (1979, 1982). A few cross-national studies on tolerance have used group-specific measures. For example, Karpov (1999a, 1999b) examines tolerance toward communists, militarists, and atheists, while Duch and Gibson (1992)'s work investigated fascists. These studies reveal similar patterns of levels of tolerance in the United States and Poland in the 1990s (Karpov, 1999a, 1999b) and across 12 Western European countries (Duch and Gibson, 1992).

A second measurement strategy in tolerance research is the least-liked or content-controlled approach. Content-controlled measures of tolerance seek to disentangle ideological orientation and tolerance (Lawrence, 1976; Sullivan et al., 1981, 1982, 1985). With this measure, respondents first pick the group that they like least from a list of possible groups. Then, respondents are asked whether they would extend civil liberties (such as the right to make a speech in the community) to their *least-liked* group. As an example, in the 1995–97 *World Values Survey* (*WVS*) (Inglehart et al., 2000) individuals were asked to name their most disliked group from the following list of choices. (The list of least-liked groups varied in a few countries, reflecting national differences in the relevance of different groups. For example, in the United States respondents were asked about immigrants without visas, right-wing extremists, Islamic fundamentalists, welfare recipients, criminals, homosexuals, and left-wing extremists. The WVS has gathered data since 1990, and as of 2014 is currently collecting its sixth wave of data in 50 countries. Regarding population coverage, the WVS gathers data from nationally representative samples from 9 out of 10 people worldwide, with some differing national samples included in different cross-sectional studies. It is viewed as the largest source of information on human beliefs and values across a wide range of social, political, and economic topics, particularly regarding how it can be used to study changes in these views. The content-controlled questions on political tolerance were included only in the 1995–97 wave.):

1. Jews
2. Capitalists
3. Communists
4. Immigrants
5. Homosexuals
6. Criminals
7. Neo-Nazis

After the respondent identified his or her least-liked group from the list of approximately seven choices, they were asked three follow-up civil liberties questions – whether members of their least-liked group should be allowed to:

1. hold public office
2. teach in schools
3. hold public demonstrations

Content-controlled measures like the one described above seek to disentangle a respondent's political ideology with their level of tolerance. That is, if a respondent leans to the left, then he or she should appear more tolerant than a right-leaning respondent if asked about the civil liberties of a leftist group like socialists. However, if the civil liberties of fascists are in question, then the right-leaning respondent may appear more tolerant. In either case, it is the political ideology of the respondent that is driving their answers, rather than their actual level of tolerance. To avoid this problem of confounding a respondent's political ideology with their level of tolerance, content-controlled measures of tolerance were developed (Lawrence, 1976; Sullivan et al., 1981). By allowing respondents to choose a least-liked group, content-controlled measures attempt to isolate political tolerance from political ideology. For some studies of tolerance, especially comparative analyses, using a content-controlled

measure is particularly important. If only a single group was considered, individual responses to that group could vary due to national differences in political history or values, rather than individual differences in tolerance. This would apply, for instance, in the case of fascists or neo-Nazis, which have a different political history in Germany than in the United States.

Research employing content-controlled measures of tolerance reveals a powerful role of context in varied settings like the established democracies of the United States, Israel, and New Zealand (Sullivan et al., 1982, 1985). Briefly, even in investigations that include controls for the content of political ideology, tolerance and intolerance are revealed to be linked to the liberty or right in question (Sullivan et al., 1982), are situationally and group-dependent (Sullivan et al., 1985), and least-liked groups are more diffuse in some countries than others where tolerance appeared to be more focused (Sullivan et al., 1985). In essence, contexts vary substantially. In addition, respondents selected least-liked groups that tended to be on the opposite end of the political spectrum from their views (Sullivan et al., 1985). A trend study using content-controlled measures has not been published to this author's knowledge given limitations of data availability described later as well as assertions that temporal variability in least-liked groups may limit the feasibility of such a work. Rather than attempting a temporal comparison, recent work has begun to use a content-controlled measure in more than a dozen countries gathered in the aforementioned 1995–97 wave of the WVS. These studies reveal striking similarities in levels of intolerance across 12, 13, and 17 countries (Guerin et al., 2004; Marquart-Pyatt and Paxton, 2007; Peffley and Rohrschneider, 2003).

A third approach to measuring tolerance gauges respondents' views on the suspension of civil liberties by the US government, minimizing sentiment toward specific groups (Gibson, 2013). Questions partially shift the focus from groups and instead query respondents about curbing civil liberties of all citizens including the right to demonstrate in military-style uniforms (Gibson and Bingham, 1985) and privacy of e-mail communication (Davis, 2007). Although less prevalent, these studies reveal some support for restrictions on civil liberties. One applies, for instance, to support for laws regarding the rights of neo-Nazis marching through Skokie, Illinois (Gibson and Bingham, 1985). Others reveal that respondents were willing to consider suspending some civil liberties in order to have greater personal safety and security when faced with the threat of terrorism in the aftermath of the terrorist attack of 9/11 in the United States (Davis and Silver, 2004). Combined, results are to some degree also contextually specific in that they are tied to particular policies.

Research on Political Tolerance: Single Country, Comparative Small and Large N Studies

Social scientists have tracked political tolerance for more than 60 years, attesting to its importance for scholarship on democracy and democratic values. Pointedly, although growing numbers of scholars and studies attest to the importance of tolerance, research reveals that not only is it a complex construct that is difficult to measure, as described in the previous section, but that it can be realized differently depending on a variety of factors like national and/or cultural contexts in addition to characteristics of individuals.

Many studies of tolerance are country-specific. For quite some time, these country-specific studies tended to focus on established democratic nations like the United States (Gibson, 2008; Mondak and Sanders, 2003; Schwadel and Garneau, 2014; Stouffer, 1955; Sullivan et al., 1979, 1981, 1982), Great Britain (Barnum and Sullivan, 1989), Canada (Sniderman et al., 1991, 1996), West Germany (Weil, 1989, 1991), Italy (Sniderman et al., 2000), and Israel (Shamir, 1991; Shamir and Sagiv-Schifter, 2006; Shamir and Sullivan, 1983). Studies of political tolerance have broadened in the last three decades to encompass newly democratizing countries including Russia (Bahry et al., 1997; Gibson, 1992, 1996, 1998; Duch and Gibson, 1992; Gibson and Duch, 1993), Poland (Golebiowska, 2009, 2014; Karpov, 1999a, 1999b), Estonia (Kaplan, 1995), and South Africa (Gibson and Gouws, 2000, 2003).

Notwithstanding recent growth, comparative studies of tolerance are less frequent in the literature, and typically focus on countries with similar political systems. Studies have explored tolerance in established democracies, comparing, for instance, the United States, New Zealand, and Israel (Sullivan et al., 1982), the United States and Israel (Shamir and Sullivan, 1983), politicians in New Zealand, Israel, Britain, and the United States (Sullivan et al., 1993), 12 and 17 Western European countries (Duch and Gibson, 1992; Weldon, 2006), and 13 former communist countries that shared a political legacy until the early 1990s (Guerin et al., 2004). Studies that explore tolerance in established and newer democracies at the same time, however, are less prevalent (cf Karpov, 1999b; Rohrschneider, 1999). A recently expanding set of works using the 1995–97 WVS attempt comparisons across a substantial number of countries (Guerin et al., 2004; Marquart-Pyatt and Paxton, 2007; Peffley and Rohrschneider, 2003). These vary, however, in the number of countries explored and range from 12 to 17 nation-states. Large N, cross-national scholarship on political tolerance that includes more than a handful of countries has recently expanded.

The majority of work on political tolerance is cross-sectional, which only provides a snapshot of tolerance that may be either group-specific or more diffuse. A few works provide a comparative or longitudinal view for the American public (Gibson, 2008, 2013; Schwadel and Garneau, 2014; Shafer and Shaw, 2009). Regarding building a comparative understanding of political tolerance across nation-states, these recent large N, comparative works are limited by large-scale data-gathering initiatives collecting indicators of tolerance across countries. Of vital importance is considering how tolerance is measured, whether it is fixed-group or content-controlled, and the extent to which individual and national or contextual factors are integrated into these works. Further, as described in the next section, while some similarities can be identified in terms of individual-level explanations of tolerance, these studies differ broadly in conceptual focus and empirical models. This variability has consequences in terms of knowledge accumulation, making

comparisons across studies difficult and to some degree hampering our understanding of political tolerance comparatively and cross-nationally. For instance, it remains possible that the levels and sources of political tolerance differ across countries and regions. These differences may be driven by contextual factors like democratic political histories and experience with the translation of democratic principles into democratic practice through internalizing democratic norms.

Major Explanatory Frameworks and Predictors Investigated

Studies of tolerance and the conceptual frameworks guiding them can be divided into those exploring individual-level theories and those examining contextual arguments related to the expression of tolerant judgments. These categories can be further subdivided into groupings of important predictors at the individual level like psychological dispositions, political orientation, and demographic characteristics and those at the contextual level including democratic learning and territorial threat.

A core set of individual-level variables typically included in studies of political tolerance include threat perception, democratic norms and activism, and demographic characteristics (Sullivan and Hendriks, 2009; Sullivan and Transue, 1999). Models of individual political tolerance often include measures of threat perception and/or fear (Duch and Gibson, 1992; Marcus et al., 1995; Sullivan et al., 1982). Disliked groups can be perceived by others as threatening to their core political values, to their social position, or to the constitutional order. In theory, threatened individuals should be more willing to put aside abstract principles of tolerance to reduce their immediate feelings of threat. Some research on political tolerance has focused on predispositions to feeling threatened (see Sullivan and Transue, 1999: 632), where some individuals are seen as psychologically more prone to feelings of threat. Other research asks about feelings of threat from the disliked group directly (Duch and Gibson, 1992; Sullivan et al., 1985).

Previous research has also stressed that political attitudes should affect political tolerance and that they may do so in more than one way (Bahry et al., 1997; Duch and Gibson, 1992; Sullivan et al., 1982, 1985). A general interest in politics might lead to an increased desire to engage complex political topics like tolerance. Also, internalization of abstract beliefs about democracy should enhance an individual's willingness to apply those norms to particular situations (Gibson, 1992; Lawrence, 1976; Marcus et al., 1995; Sullivan et al., 1982). Political ideology or left/right placement on the political spectrum may also affect tolerance. The findings on political ideology are mixed, however, linked with whether a group-specific or content-controlled measure was used (Duch and Gibson, 1992; Sniderman et al., 1989; Stouffer, 1955; Sullivan et al., 1982). In addition, individuals who directly use civil liberties may be more tolerant. That is, individuals who display 'democratic activism' by making use of their freedom to associate, right to free speech, or freedom to protest, practice their civil liberties and should therefore move beyond tolerance in principle to true increased levels of tolerance (Peffley and Rohrschneider, 2003; Guerin et al., 2004). Finally, demographic characteristics like age, gender, and religion have also been linked with tolerance (Stouffer, 1955; Sullivan et al., 1982, 1985).

These individual-level explanations of tolerance share an emphasis on learning tolerance. Individuals can acquire political tolerance much as they acquire other democratic norms – through contact with democratic institutions. That is, exposure to institutions in a democratic society increases exposure to the dominant democratic norms, which encourages political tolerance. As an example, the effect of education on political tolerance is an example of a learning effect. Individual education increases familiarity with diverse ideas and with diverse people. At the same time, educational institutions in a democratic society socialize individuals to democratic norms (Weil, 1991). Stouffer's (1955) seminal work on tolerance identified education as a crucial predictor of tolerance, and the effect of education has been demonstrated in many subsequent studies. Generally, increased levels of education should lead to increased levels of tolerance.

The recent availability of opinion data for more than a handful of countries has led to renewed focus on the democratic learning perspective. Moving beyond individual-level explanations, studies emphasize democratic institutions and how similarities and/or differences in the levels and sources of political tolerance may be best understood. For instance, citizens living in established democratic societies may have more opportunities to have contact with democratic institutions or engage in the 'rough-and-tumble' of democratic politics (Peffley and Rohrschneider, 2003). The democratic learning hypothesis would suggest that lower levels of tolerance in Eastern Europe result from these countries' lack of experience with democracy, such that citizens may not yet have learned how to translate general democratic values into applied tolerance. The longevity of democracy in a nation constitutes an important contextual feature. For instance, as noted earlier, three recent studies use the WVS. These studies revealed lower levels of political tolerance to be widespread in postcommunist countries in Eastern Europe (Guerin et al., 2004; Marquart-Pyatt and Paxton, 2007), and that factors typically associated with tolerance in the United States replicated weakly in other countries, notably so in Eastern Europe (Guerin et al., 2004; Marquart-Pyatt and Paxton, 2007; Peffley and Rohrschneider, 2003).

Recent work has identified important themes comprising emerging areas of interest worth noting including how widespread intolerance is within established and nascent democracies, how tolerance might shift over time and/or across groups, and the continuing relevance of the measurement of tolerance for comparative and cross-national research. Although empirical investigations are constrained by the availability and quality of existing data, prospects for future research on political tolerance are promising. A growing number of countries and questions tapping into democratic values like tolerance have periodically been added to existing data-gathering initiatives like the Eurobarometer Surveys, The European Values Survey, GSS, the International Social Survey

Program, and the WVS, making new comparisons possible. In addition, as knowledge is gained about the possibility of contextual and individual explanatory factors being salient, analytical techniques being applied to this stream of research are becoming increasingly sophisticated. For instance, multilevel or hierarchical linear modeling offers numerous advantages to cross-national, comparative research on a range of important topics, including tolerance.

Concluding Thoughts for Future Research

Recent scholarship lays a promising yet challenging foundation on which subsequent studies might build. These thematic areas include variability among established and newer democracies, multiple ways of measuring political tolerance and intolerance, and the question of the extent to which least-liked groups may have changed over time within a single country. As was described in the previous section, future work can potentially take on at least two possible forms: (1) comparing within established democratic countries over time using fixed-group and content-controlled group measures and (2) comparing across democratic regimes and time to advance our knowledge about the level and sources of political tolerance in comparative and cross-national context. Given existing data infrastructures, future research is likely to continue along at least the following three lines. First, single-country or case studies that include a significant temporal element are increasingly probable (Schwadel and Garneau, 2014). Second, the number of studies comparing across countries is also likely to grow. A third, possible emerging area is scholarly work that embarks on comparisons across datasets (i.e., of more than one cross-national secondary dataset), offering a promising addition to the existing literature on tolerance in the American public (Gibson, 2013). Although challenges remain for political tolerance worldwide, the implications of intolerance and its potential for restricting civil liberties are important for established and unconsolidated democracies.

Political Trials

Leora Bilsky, Tel Aviv University, Tel Aviv, Israel

Abstract

This article discusses the theory and practice of political trials in liberal democracies as distinct from 'show trials.' It explores the dilemmas raised by such trials when they occur in transitions to democracy, within established democracies, and in international and transnational trials of atrocity, and explains scholars' call to recognize the inevitably political character of legal proceedings.

The term 'political trial' is popularly associated with 'show trials' like the Moscow Purge trials conducted by Stalin during the 1930s. Such trials represent an extreme example of political repression and are viewed as sham legal proceedings designed by authorities to dramatize specific political campaigns and/or to eliminate prominent individuals. In this context, the political trial is taken to be a 'show' in which politicians and not jurists pull the strings and determine the results of the trial in advance. This pejorative use of the term also helps designate regimes that resort to such techniques as the antithesis of liberal democracies. Yet, as Otto Kirchheimer observed, the most effective usage of political trials occurs precisely within liberal democracies, in societies committed to the rule of law. What can explain this gap between popular perceptions and the actual practice of political trials? Can we distinguish a political trial from a 'show trial'? Should we continue to view political trials as opposed to the very essence of liberal democracies, or should we accept them as part and parcel of this system, deserving a sustained theoretical elaboration?

In his seminal book *Political Justice*, Kirchheimer defines political trials as instances in which "court action is called upon to exert influence on the distribution of political power" (Kirchheimer, 1961: p. 49). This broad definition includes the use of the court by the ruling elites or by out-groups and dissenters to achieve political goals by judicial means. Many writers regard the central factor in such trials as the political motive behind them. The connecting thread between the trial of Socrates for corrupting the youth of Athens (399 BC), the trial of Jesus for blasphemy and sedition (AD 30), the trial of Joan of Arc (1431) for heresy and witchcraft, the trial of Thomas More (1534) for remaining silent when asked about Henry VIII's supremacy in religion, the trial of Galileo (1633) for heretically suggesting that the earth moved around the sun, and many other trials is that, in each case, men in power believed that the defendant was a threat to them (Becker, 1971; Belknap, 1981). For this reason the prototype of a political trial has been the criminal trial of a political adversary for political reasons. This broad definition encompasses trials in which the defendant has directly attacked the established order by acts such as treason or sedition, but also trials involving common crimes in which only the personality or the motive of the offender indicates their political nature. Other writers try to refine this definition by expanding its scope to legal proceedings other than criminal trials such as impeachment, congressional hearings, and truth commissions. It has also been suggested that the definition be extended to include trials involving larger group conflicts such as ethnic, race, or labor struggles. Some move the emphasis from the political motive of the authorities to the political identity of the defendant. Others conclude that the important factor that distinguishes such trials is not the motive but the competition of stories over the identity of the polity. Notwithstanding their differences, all writers on the subject agree that political trials are inevitable not only in authoritarian regimes but also in constitutional democracies, although this is generally denied, in particular by legal practitioners. Critical of such denials, these scholars set out to replace them with an honest recognition of the existence and function of political trials in both types of regimes.

Why should the term 'political trial' cause such anxiety and widespread denial? Because law tends to stabilize the status quo, it is not surprising that there are always people who feel justified in ignoring the law in order to bring about drastic and necessary changes. This is especially true for powerless groups that are prevented from participating effectively in important institutional decisions affecting their lives (Hakman, 1972; Fletcher, 1995). When the authorities put on trial those who challenge the basic value distribution in society, especially those who are willing to disregard existing laws to this end, the result is a political trial. Despite this regular occurrence of political trials within democratic societies, the term is widely resisted because of its connotation with 'show trials' in which either the charge is a 'frame-up' to conceal the political motivation of the prosecution, or the hearing itself fails to meet minimum standards of judicial impartiality and independence. For this reason, writers attempt to distinguish among different types of political trials. One classification distinguishes among politically motivated trials, politically determined trials, and trials with substantial political consequences (Friedman, 1970). Another differentiates between political 'trials' (abridgment of due process guarantees), the 'political' trial (camouflaged as a criminal trial), and the political trial (politically motivated) (Becker, 1971). These efforts at classification have proved frustrating because of the immense historical variations and the widespread existence of political trials in very different regimes. Writers have identified a variety of characteristics of political trials but none has proved to be a sufficient and necessary condition. This literature has largely been descriptive but has failed to assess the compatibility of political trials with liberal values and thus to overcome the negative connotations the term arouses. In order to address

this question, it is necessary to expose the hidden engine of political trials – their legitimizing function – and its relation to democracy.

The legal system offers a tempting opportunity for those in power to damage enemies, tarnish their image, and isolate them from potential allies by casting them as criminals. This temptation becomes especially strong in democracies that constrain the ruling elite from resorting to more direct devices of repression. What distinguishes political trials from other political devices is their legitimizing function, that is, their ability to turn a political adversary into a criminal defendant and thereby reinforce the legitimacy of those in power. However, this function can be served only if the public perceives the trial as providing the defendant with a 'fighting chance.' In constitutional democracies, this 'fighting chance' is generally assured by the relative autonomy of the judges and the constraining effects of the rule of law (Kirchheimer, 1961). Moreover, these guarantees introduce an element of uncertainty into the trial, and encourage political defendants to use it to expose the illegitimacy of the policy or value system advanced by the authorities. Indeed, from Socrates's trial (399 BC) to the Chicago Conspiracy trial (1969), there have always been defendants who have exploited the limited forum that the political trial provided them to articulate their oppositional views. Some have adopted a defiant stance, proclaiming their right to commit the crime (Solomon Tellirian – as a protest against the Armenian massacre by the Turks in 1921; Dr Jack Kevorkian – advocating euthanasia in 1999), or refusing to respect traditional courtroom decorum altogether (Bobby Seale – Black Panthers in 1969; Klaus Barbie – Nazism and Vichy France in 1987); others have played by the rules in order to win an acquittal that would confirm their claim that they were being prosecuted for their political beliefs (Dr Spock – Vietnam War in 1968). Insight into this legitimizing function and the element of uncertainty that it introduces into political trials in democratic regimes exposes the tension between politics and justice inherent in them. This has made political trials a fascinating area for research since the 1960s.

Political Trials in the Transition to Democracy

Political trials are most salient in times of transition between regimes, especially when a new democratic regime confronts crimes of the old regime. Indeed, the first attempts to seriously consider the compatibility of political trials with liberal democratic values appear in the literature on the transition to democracy. Unlike a military revolution that sustains its authority by brute force, democratic regimes are committed to the rule of law and are inclined to address the evils of the previous regime with the help of legal devices. However, the new regime's commitment to the rule of law also makes it aware of the dangers of using ex post facto laws and indulging in 'victor's justice.' At such times, the various expectations from the law – to punish the guilty, ascertain the truth about the old regime, and enhance reconciliation in society – seem to overwhelm the legal system and to push it in opposite directions. Moreover, the forward-looking direction of the architects of democracy who are concerned with the efficacy of the transition often conflicts with the backward-looking direction of legal proceedings and their narrow focus on individual guilt (Osiel, 1997; Nino, 1991; Teitel, 1997). For these reasons, trials of transition bring to the foreground the clash between politics and justice. Two main approaches to the problem have evolved since World War II: exemplary criminal trials and truth commissions, both of which can be considered political trials of sorts and have received extensive theoretical elaboration.

At the end of World War II, the Allies established an international military tribunal in Nuremberg (1945) to judge the leaders of the Nazi regime. This was the first time in history that the leaders of a defeated country had faced criminal prosecution for war crimes, crimes against the peace, and crimes against humanity by an international tribunal. The charge applied in the trial – conspiring to wage an aggressive war – allowed the prosecution to tell a general historical narrative. Could the obvious political end of using the court to teach a history lesson (through ex post facto laws, and victors' judges) be reconciled with the demands of liberalism? Confronted with this dilemma, Judith Shklar made the first serious effort to reconcile the legacy of liberalism with political trials occurring in the transition to democracy (Shklar, 1964). A legalistic understanding of liberalism, she argued, could justify the Nuremberg trials only at the high cost of denying their political nature altogether. In her view, procedural safeguards to defendants could only guarantee that the trial would not deteriorate into a show trial, but this in itself could not justify deviating from basic liberal demands such as an independent judiciary, established court, nonretroactive laws, and so forth. Paradoxically, Shklar came to the conclusion that the political dictate of founding a democracy justified the divergence from strict legalism in the Nuremberg trials. In other words, it was only an honest recognition of the political aspects of the trials, their educational and symbolic contribution to the building of democracy in postwar Germany, that could justify them. Later writers accepted Shklar's consequentialist approach to transitional justice but limited its applicability to trials that guarantee the due-process rights of the defendants (Osiel, 1997).

A very different attempt to address the crimes of the Nazi regime was made in the Eichmann trial (1961). This time it was not the international community but an Israeli court that undertook to judge one of the central figures in the massacre of the Jews. The political nature of the trial was evident, among other things, from its reliance on the particularistic law of 'crimes against the Jewish people.' Likewise the heavy reliance on victims' testimonies about their suffering (and through them the telling of the Jewish Holocaust) conflicted with the liberal demand that the trial concentrate on proving the deeds of the accused. Hannah Arendt and other writers criticized the Israeli prosecution for politicizing the trial in this way (Arendt, 1963; Segev, 1993; Lahav, 1992). Others see the decision as stemming from the general dilemma of political trials of how to strike a balance between the need to establish the truth about an oppressive regime, the need to give voice to the victims, and the need to ascertain the guilt of the defendants (Bilsky, 2004).

This dilemma is compounded when the former authoritarian regime retains enclaves of power and opposes any attempt to bring to justice the officials of the former regime. In South America, Argentina is one of the few nations to have

prosecuted military officers in public trials for their role in repression carried out under the former regime. The political nature of these trials was evident in the decision to prosecute only the masterminds and the worst offenders, and in the greater priority given to the value of learning about the evils of the authoritarian past than to prosecuting every individual who was involved. Again, the justification for such selective prosecution is given in consequentialist terms – the extent to which the trial serves to strengthen the emerging democracy (Nino, 1991). A central dilemma that emerges in transitional trials of this kind is the breakdown of common discourse, which undermines the legitimacy of the trial for some segments of society. Thus, the Argentinian court's decision to limit the evidence to proving the deeds of the accused, without allowing them to be situated within the wider historical narrative about an alleged war of self-defense against attacks on the regime by guerrilla forces, was deemed political and undermined the legitimacy of the trial in the eyes of the military (Osiel, 1997).

Alongside efforts to bring to trial leaders of former authoritarian regimes for gross violations of human rights developed the institution of truth commissions established by national or international organizations. Truth commissions reduce the tensions that arise in transitional trials by separating the various functions of learning the truth about the past, of ascertaining individual guilt, and of giving voice to victims. The Truth and Reconciliation Commission in South Africa, for example, was divided into a Committee on Human Rights Violations (victims' testimonies), a Committee on Amnesty (offenders' testimonies), and a Committee on Reparation and Rehabilitation. In each committee, different procedures were used (1995 Act). It further made the granting of individual amnesty conditional upon providing a full account of the offenses committed (Minow, 1998). Truth commissions have proved to be far more effective than court proceedings in furnishing a dramatic medium for theatricalizing the new official history, because the narratives of victims are rarely interrupted by lawyers and there are incentives for offenders to relate their part in the repression. Indeed, in several countries the commission's proceedings have been broadcast daily, and in others the final report has become a bestseller (Brazil, Argentina). Truth commissions present us with a kind of political trial in which the balance between politics and justice has been struck in ways more compatible with liberal concerns. However, the adoption of the discourse of healing by truth commissions has been sharply criticized for drawing attention away from the political context in which abuse is committed, as well as signaling that the commission of mass crimes does not carry serious consequences (Leebaw, 2011).

Political Trials in Established Democracies

The political nature of transitional justice stems from the fact that there are no overarching legal norms that are accepted as legitimate by the two successive regimes. Moreover, in these cases the trials have overwhelmingly been used to fulfill social and political functions other than ascertaining individual guilt. Liberal scholars, as we have seen, have been willing to recognize the political nature of such trials and to justify it, but have not extended their theories to trials in established democracies. The general view is that in normal times law should endeavor to keep politics out of the courtroom so that every political trial is perceived as a corruption of the rule of law (which may be termed the 'pathology thesis'). This distinction, however, fails to account for the striking similarities between transitional situations and periods in which there has been a significant increase in political trials in democratic societies.

In the United States, political trials have occurred whenever the status quo has been challenged, generally during periods of social and political ferment unleashed by such forces as war, economic conflict, or racial discord (Belknap, 1981). For example, the decade that began with the escalation of the Vietnam War in 1965 brought an epidemic of political trials culminating in the Chicago Conspiracy trial (1969–70). This case represents a microcosm of American political justice of the era, as it was directed against representatives of major antiwar groups, youth counterculture, and the Black Panther Party, who all believed that the war was illegal and sought to mobilize the public against it. Although the charges were clearly political (conspiracy to cross state lines with the intent to incite riot), the trial also demonstrated the ability of the defense to politicize the trial and turn it into a forum for social protest by flouting the norms of the courtroom and ridiculing the judge (Ely, 1981). In such trials as the Chicago Conspiracy trial, the same breakdown of common discourse was manifested as in political trials during transitions to democracy.

The social turmoil and political trials of the late 1960s influenced the development of radical theories of law (Gordon, 1982), as scholars in critical legal studies, critical race theory, and feminist legal studies began to question the plausibility of the liberal ideal of separating law from politics. For these scholars the very attempt to delimit the boundaries of the category 'political trials' obscures the way in which politics enters every trial and every field of law. They argue that the liberal reliance on a distinct category of political trials often serves to legitimize the status quo. Critical theory understands politics not in the narrow sense of the term (motive of authorities, identity of defendant, and so forth) but as the hegemonic ideology that shapes the interpretation of law while presenting it as neutral. The main contribution of critical writings to understanding political trials has been their rejection of the 'pathology thesis' about the relation between law and politics and their systematic efforts to uncover the ideological structures that shape different areas of law (Kelman, 1987; Kairys, 1982). This broad definition of political trials, however, had its drawbacks because it no longer called for a systematic investigation of the unique features of classic political trials, and shifted the attention of scholars from the court drama and social reception of the trial to the appellate court interpretation of the law.

Other scholars, still committed to the liberal framework, have identified a new form of political trial that emerged during the 1980s and 1990s. While in the old political trial the ruling authorities selected certain individuals to stand for an opposition that the state wanted to eliminate, in the new political trial a section of the public turns the trial into a political trial by identifying with the victims (who are not a formal party to the trial) or with the defendant. In these cases, the state does not intend a political trial and has very little control over its

politicization (Fletcher, 1995). The people mobilized around these trials are usually out-groups protesting their marginalization by the legal and political institutions. Examples are famous rape trials and self-defense trials of battered women who killed their abusive spouses in which women's groups identified with the victim and politicized the trial. The Rodney King trial and O.J. Simpson trial likewise became political trials in which African-American groups were mobilized to protest against white justice in America. The study of these trials draws particular attention to the role of the media in these cases.

The focus on group conflict and on the narrative and rhetorical aspects of political trials in ongoing democracies provides scholars with the key to understanding their dynamics from a pluralistic perspective. The famous trials of Socrates, Jesus, Dreyfus, and others are examples of heroes unjustly prosecuted, but they can also be viewed as major junctions in the life of the republic where society's conflicting values are played out not only, and not even mainly, through the learned interpretation of the law but through the human drama in and around the courtroom. In these trials, the social conflict is transformed into competing narratives that capture the public's attention and offer an opportunity for collective self-reflection. Through an examination of competing values and loyalties they bring together for public consideration society's basic contradictions (Christenson, 1999). From this perspective we can see how political trials, while threatening the rule of law, at the same time may contribute to the development of a more critical and democratic society.

Political Trials in the Transnational Legal Order

As we saw, although the Nuremberg trials were condemned as victors' justice, the Eichmann trial was criticized as victims' justice. Ironically, in the 1990s Nuremberg was invoked as the most important precedent for the establishment of ad hoc international criminal tribunals and a few years later the permanent International Criminal Court (ICC). The Eichmann trial became a precedent for the exercise of universal jurisdiction by domestic criminal courts. In both cases, the justification for turning to courts outside the national jurisdiction with closest links to the crimes was to end impunity, that is, to counter domestic politics' ability to obstruct the wheels of justice. This turn was accompanied by a growing reliance on a new legalism connected to the human rights discourse. At the center of these trials stood the new crimes of genocide and crimes against humanity, viewed as supranational crimes exploding spatiotemporal legal coordinates by overcoming prescriptive periods and territorial limits to criminal jurisdiction (Douglas, 2007).

Underlying these developments in international criminal law is an unarticulated assumption about political trials: if the danger of impunity came from too much proximity to domestic politics, a cure was to be found in distancing the tribunal from the influence of the political authorities. In other words, the turn to third party criminal courts and international tribunals was meant to ensure the triumph of the rule of law over political considerations. However, far from ending the debate about political trials, new criticism was raised by famous defendants, such as former Chilean dictator General Augusto Pinochet, former Yugoslav president Slobodan Milosevicz, and former Israeli prime minister Ariel Sharon, who claimed to be the victims of a new form of show trial. International criminal law thus poses the following puzzle: are international tribunals and third party criminal courts the source of danger of the politicization of international law, or are they the best guarantee against 'political justice,' piercing the shield of sovereign immunity?

I explore this question by examining the new political trial in its three contemporary manifestations: third party domestic courts exercising universal criminal jurisdiction, international criminal tribunals, and transnational tort actions brought by victims in third party civil courts.

Universal Jurisdiction by Domestic Criminal Courts

If the problem of political trials was attributed to too much proximity to the political authorities, can too much distance produce new dangers of politicization? During the 1990s, frustrated groups of victims discovered the tool of universal jurisdiction, first recognized by the Eichmann court, which had remained dormant throughout the Cold War, as a way to seek justice in foreign courts. Prosecutors further relied on legal doctrines such as crimes against humanity and genocide, which have been interpreted by some national courts as not being subject to statutes of limitation. However, this development created new dangers of politicization. The removal of territorial and temporal limitations on prosecution makes the legal process vulnerable to political opportunism in the timing of the prosecution. For example, Ariel Sharon faced the possibility of trial in Belgian courts in connection with the 1982 Sabra and Shatila massacre in Lebanon, following complaints brought only after he was elected prime minister of Israel, 20 years after the massacre. Ordinary prescriptive periods force the prosecution to bring charges as soon as possible and to concentrate on the strength of the legal case, thus precluding political considerations of this kind. Yet understanding the significance of crimes of such magnitude may require the passage of long periods of time and the changing of generations, lending support to the relaxation of procedural constraints on prosecution.

Another sense of politicization that undermines more profoundly the integrity of the criminal process stems from the disjunction that universal jurisdiction creates between the judge and the relevant political community. This disjunction operates at two levels. First, critics worry that allowing foreign judges to adjudicate cases related to societies to whom they are largely unaccountable threatens the democratic foundations of criminal law (Orentlicher, 2004). Second, since the courts exercising universal jurisdiction operate at a remote distance from the communities that are deeply affected by their judgment, the solidarity between judge and community is undermined, thus weakening in the eyes of the community the legitimacy of the judges who do not take the risk of living under the results of their judgments. This problem is exacerbated in cases in which the judge fails to appreciate the intricacies of the cultural, political, and historical context of the case. We are used to thinking about the rule of law in terms of maintaining a distance between the court and the parties to the dispute, but at the same time the rule of law requires that a meaningful link be established between the

court and the community injured by the deed. It seems that underlying this tension is a basic assumption that the criminal law belongs to a political community and is an exercise in self-governance.

In the eyes of supporters of universal jurisdiction, the dangers of unaccountable sovereign power seem to outweigh these new dangers of politicization. That position, however, takes for granted that the two alternatives are exhaustive. A middle ground can be found in the requirement of a meaningful link to the court, recently added by legislators and courts, in response to the political uses of universal jurisdiction made during the 1990s (Bilsky, 2010). Similarly, the Princeton Principles on Universal Jurisdiction, a set of nonbinding guidelines drafted by jurists in 2001, recommend that in case of competing national jurisdictions, weight be given to the place of the commission of the crime and the nationalities of the alleged perpetrator and victims, among other factors (Principle 8 of the Princeton Principles on Universal Jurisdiction).

Criminal Trials in International Criminal Courts

International criminal tribunals appear to enjoy more legitimacy than domestic criminal courts exercising universal jurisdiction, as they are the product of consent (where the country is a party to the treaty establishing the ICC, or the case is self-referred) or the will of the international community (where the case was referred by the U.N. Security Council). Yet the distance between judge and community raises some of the same problems as universal criminal jurisdiction, and therefore also calls for ways to reconnect the relevant community to the trial. We can view the principle of complementarity embedded in the Rome Statute establishing the ICC as aspiring to find a middle ground between universality and territoriality. By providing that a case is inadmissible before the ICC if it is being investigated or prosecuted by a state having jurisdiction over it, this gives priority to national courts in trying the case (Holmes, 1999). When there is such an investigation or prosecution, the ICC can take up the case only when the state "is unwilling or unable genuinely to carry out the investigation or prosecution" (art. 17 of the Rome Statute). This mechanism provides strong incentives to states to prosecute crimes they would have preferred to ignore, nevertheless leaving the door open for the ICC to intervene in exceptional cases. The principle of complementarity therefore appears to address the problem of sovereign impunity while limiting the dangers of politicization that arise from the distance between the trial and the concerned community. However, a recent study of compliance and resistance to the Inter-American Court among domestic judges suggests that a referral system such as the one created by the European Court of Justice might lead to greater compliance (Huneeus, 2011). Another middle ground is achieved in 'mixed' or 'hybrid' tribunals, staffed by both national and foreign judges and prosecutors, and likewise blending international and national criminal procedural law (Shraga, 2009).

Is the ICC immune, then, to political uses? The U.N. Security Council's significant role in the establishment of international criminal tribunals (the International Tribunal for the Former Yugoslavia, and the International Criminal Tribunal for Rwanda) and its power to make referrals to the ICC certainly provide openings for political considerations in the choice of situations brought to justice. Critics point to the fact that, to date, the ICC has only investigated crimes committed by Africans. But it is not only powerful states that can draw political advantage from these trials. Domestic authorities too can use ICC proceedings for political purposes, even though they do not control the decision to prosecute (this decision is taken by the ICC's prosecution office). If Kirchheimer's classic definition of the political trial is the use of legal means for political ends, turning political adversaries into criminal defendants and thereby reinforcing the legitimacy of those in power, recent research on the local impact of ICC prosecutions related to Sudan and Uganda reveals the same dynamic (Nouwen and Werner, 2012). According to that study, the Ugandan government referred rebel movements to the ICC as part of a military strategy, in the hope that the ICC could capture the rebel leaders. Moreover, the government successfully used the proceedings as part of an international reputation campaign in which rebels came to be branded as internationally wanted 'criminals' while the Ugandan government could portray itself as a friend of humanity. Although referral carried the risk identified by Kirchheimer that Ugandan government officials themselves be prosecuted, the government's reputation campaign succeeded in silencing criticism of its actions in the Congolese territory, which the ICC prosecutor has not investigated (Nouwen and Werner, 2012).

Thus the question is not whether international criminal trials are political, but what are the characteristics of the new political trial that emerges from the ICC. Nouwen and Werner have pointed to the fact that because the court is international and not controlled by domestic authorities, it provides new possibilities for political opponents to initiate the trial through referrals. Yet in their view this heightened risk to the government is balanced by the fact that international officials, not victims, control the proceedings, together with the Court's dependence to a large degree on the cooperation of the relevant national government for numerous procedures, including the enforcement of arrest warrants and the issuance of visas to ICC staff. The dependence on state cooperation may also lead ICC staff to play into the friend/enemy of mankind dichotomy used by national governments. This institutional interest in being in good relations with the authorities is exacerbated by the ICC's concern with establishing its own legitimacy as an international court. The fact that contrary to the tribunals established at Nuremberg, the ICC can adjudicate atrocities even as an armed conflict is ongoing further raises the political stakes of the ICC's interventions. These political aspects specific to international tribunals are obscured by the universalist vocabulary of crimes against humanity, which itself might intensify political struggles. In other words, although the dynamics of international political trials are analogous to those in the domestic sphere, the stakes are much higher as the ruling of an international court brands the defendant as an enemy of humanity, leaving little space for political contestation or deliberation.

The distance of the ICC from the relevant political community enables it, on the other hand, to attend to victim groups that are often excluded or persecuted by the political authorities. Thus, the Rome Statute has enshrined victims' rights to both protection and participation in the ICC's

proceedings, through a range of procedural rules and mechanisms, and the creation of a special Victim and Witness Unit charged with coordinating protection measures. However, victim participation does not amount to control of the case, which remains in the hands of the prosecution. Moreover, because the ICC's legitimacy depends in part on the claim that it is acting on behalf of victims, proceedings tend to emphasize victims' innocence, obviating any discussion of 'imperfect' victims who collaborated with the regime. This leads to criticism that the ICC remains legalistic and fails to address the gray zone between perpetrators and victims that characterizes collective crimes (Leebaw, 2011).

Transnational Tort Human Rights Litigation in Domestic Courts

We have seen that much of the denial of the political nature of trials and the reemergence of legalism is connected to the form of the criminal trial. Can civil proceedings allow for a better legal treatment of mass violence? Can they end impunity by creating a direct channel for victims to bring charges against state officials without the filter of a public prosecutor? Since the 1980s, victims of grave human rights abuses have invoked the Alien Tort Statute of 1789, which grants US federal courts "jurisdiction of any civil action by an alien for a tort only, committed in violation of the law of nations or a treaty of the United States" (28 U.S.C. §1350). The US courts have generally interpreted this statute as enabling them to exercise a form of universal civil jurisdiction, by opening the door to cases unrelated to the United States. These claims filed by individuals as well as classes of victims have targeted both low-level state officials and prominent politicians (such as former Filipino dictator Ferdinand Marcos), sometimes in parallel to international criminal prosecutions. Thus, former Bosnian Serbian leader Radovan Karadzic was sued under the Alien Tort Statute and later indicted by the International Criminal Tribunal for the Former Yugoslavia, in both cases for war crimes committed in Bosnia. This type of litigation has also redirected attention to a new sort of defendant: the multinational corporation, accused of supporting or enabling atrocities committed by state authorities. Alien Tort Statute litigation therefore holds the promise of greatly reducing impunity, by not only distancing the legal process from the relevant political community as in universal criminal jurisdiction, but also by avoiding reliance on a public authority to bring a claim and targeting not only individuals but also the corporations that enable mass violence.

However, privatizing prosecution by granting full control of the litigation to victims creates new types of politicization. Organized groups of victims can dominate the proceedings at the expense of other victims. For example, in restitution cases brought against Swiss and German corporations for participation in the Nazi crimes, Jewish organizations tended to predominate over other victim groups (Adler and Zumbansen, 2002). A different problem arises from the lack of screening by a public prosecutor, which shifts to the court all political discretion in allowing the case to proceed. Although this has led many to condemn Alien Tort Statute litigation as court interference in foreign policy, others have countered that various legal doctrines reduce the possibility of a clash with US foreign policy, and that in any event the strict conditions imposed by the US Supreme Court means that in practice very few cases succeed. Nevertheless, the very filing of a lawsuit by victims might paralyze the political process in cases of transition to democracy. Furthermore, damage awards to victims might conflict with the distributive plans of transitional governments. One such example is the class action against Marcos, where a US jury granted a class of 10 000 victims of torture damages in excess of 2 billion dollars. Although legally a success, the victims have collected very little of the damage award, in part because of conflicting claims to the Marcos's fortune by the democratic government of the Philippines. Although some writers argue that the real contribution of the civil lawsuit is symbolic rather than material, even symbolic victories have political implications, potentially empowering victims but also enabling some victims to the exclusion of others to affect the domestic political agenda.

Unique to civil litigation is the possibility of settlement. The settlement of Holocaust-related claims by groups of victims against European corporations was criticized for undermining the normative functions of the court as well as the didactic functions of clarifying history and shaping collective memory (Marrus, 2009). Moreover, observers unaccustomed to American class action practice perceived the negotiation process and the monetary settlements that followed as victories of political pressure over the rule of law (Marrus, 2009). Others counter that it is precisely the American class action that gave victims the necessary leverage against giant corporations that had enjoyed *de facto* immunity for decades due to their political lobbying in Europe (Bilsky, 2012a). Moreover, settlement provided the flexibility required for dealing with complex political issues and the admission of moral responsibility in situations of collaboration with authoritarian regimes. It also released the judge from the controversial role of creating official history by incentivizing private corporations to investigate their past and publish new histories (Bilsky, 2012b). Yet this new power of corporations to create soft law and commission history raises new concerns about the political use of legal proceedings by corporate actors.

The possibility of suing individuals and corporations under the Alien Tort Statute appears to have been seriously restricted by the 2013 decision of the Supreme Court in *Kiobel v. Royal Dutch Petroleum*, in which it was held that the statute should not be interpreted to apply to conduct outside the United States. Nevertheless, it is now apparent that civil litigation is crucial for addressing the involvement of larger sections of society, including business entities, in collective crimes, and the creation of a globalized class action might be considered in parallel to the ICC.

Conclusion: Is the Political Trial Still a Relevant Category?

If we accept – following Shklar, Douglas, Bilsky, Nouwen and Werner, and others – that trials, whether domestic, international, transnational, criminal, or civil, inevitably have political consequences, the question of whether a trial is political obscures more than it reveals. Instead, we should ask what sort of politics each mechanism promotes, and what kind of procedures and legal doctrines are available to the court to

balance the politics while fighting niches of immunity. The question, in short, is not, "Is law political?" but "What sort of politics can law maintain and reflect?" (Shklar, 1964: p. 144). It seems that trials addressing collective violence inevitably have substantial collective significance, and attention should therefore be turned to finding ways to harness the law so as to foster participatory democracy. Enhancing the participatory character of legal proceedings is particularly pressing at a time when the nation-state is weakened and new transnational political actors carve for themselves areas of power without corresponding responsibilities.

Abstract

Political participation refers to voluntary activities undertaken by the mass public to influence public policy, either directly or by affecting the selection of persons who make policies. Examples of these activities include voting in elections, helping a political campaign, donating money to a candidate or cause, contacting officials, petitioning, protesting, and working with other people on issues. Particular activities cluster into modes of participation. Substantial cross-national data have shown that wealthier and better-educated people participate at higher rates than the less advantaged, although this relationship is weaker in countries where strong parties or other political organizations provide alternative resources. Research associated with the Civic Voluntarism Model (CVM) has documented that people transfer to political activity skills which they acquire in organizations. The CVM and other recent studies have also demonstrated that people participate more in response to recruitment or mobilization. (Both terms refer to efforts by one person to increase the activity of another.) The Political Action project has shown that people have expanded their 'political action repertory' to encompass both protest and conventional participation. The patterns of participation in authoritarian regimes and in economically less-developed countries raise other issues but substantially follow these broad outlines.

Political participation refers to the activities of the mass public in politics, including, for example, voting in elections, helping a political campaign, giving money to a candidate or cause, writing or calling officials, petitioning, boycotting, demonstrating, and working with other people on issues. Political participation figures in philosophical discussions of democracy and representative government since ancient times because it provides the means for citizens to communicate their views. Normative interest in the topic remains vigorous (*see* Democratic Theory). This article focuses upon the empirical study of political participation. Scholars look for systematic patterns that explain why some individuals are inactive and why others choose certain activities. The patterns reflect the political context and both reflect and affect the structure of political power.

Participation provides the link from the mass public to the political elite who are presumed – and sometimes shown – to respond (*see* Political Representation).

Differing Definitions of Participation

Scholars differ in their definition of political participation. The currently dominant view limits participation to actions that might affect others, as in the following definitions. "By political participation we mean activity by private citizens designed to influence government decision-making" (Huntington and Nelson, 1976, p. 3). "By *political* participation, we refer simply to activity that has the intent or effect of influencing government action – either directly by affecting the making or implementation of public policy or indirectly by influencing the selection of people who make those policies" (Verba et al., 1995, p. 38). The restriction to private citizens is meant to exclude from the concept activity undertaken in their official capacity by those for whom politics and governing are a vocation. A few scholars (cf Milbrath, 1965) include political involvement and activities to support the regime as participation. For these scholars, reading about politics is also political participation, while under the dominant definition it is not (since it does not have direct effects on others).

Another definitional debate in the field concerns the extent to which actions that have the effect of influencing policy without that being the actor's intent also count as political participation. Adopting the more common view, Verba et al. (1995, pp. 38–39) restrict their study to voluntary activity, which they define as follows: "By voluntary activity we mean participation that is not obligatory – no one is forced to volunteer – and that receives no pay or only token financial compensation." In contrast, Huntington and Nelson (1976, p. 7) explicitly include not only *autonomous* participation but also *mobilized* participation, defined as "activity that is designed by someone other than the actor to influence governmental decision-making." Under that definition, they would include as a participant a worker who attends a rally because his boss threatens to demote him otherwise, even if the worker has no intent of affecting government. In practice, it can be difficult empirically to distinguish mobilized from autonomous activity. For answering questions about the impact of participation upon political outcomes, the two are equivalent. The distinction is useful, however, when one focuses on the motives for participation or the impact of participation upon the actor.

The Study of Participation

Participation as Electoral and Hierarchical: Early Studies

The modern empirical study of political participation began developing in tandem with the modern study of electoral behavior using sample survey data. Election outcomes depend not only upon people's preferences but also upon which citizens choose to exercise their preference at the polls. Partially reflecting that link, many of these studies truncated political participation to electoral participation, that is, voter turnout

and occasionally some campaign activities (*see* Voting: Turnout). Much empirical work was done in the United States, and much of that was connected to the Michigan Survey Research Center, especially under the leadership of Warren Miller and Philip Converse. These investigators also collaborated with colleagues outside the United States, especially in Europe, producing further studies addressing participation, especially voting. Under the leadership of Stein Rokkan, Scandinavian scholars produced a substantial body of work on participation as part of their more extensive studies of political behavior (see for example Rokkan, 1970). These studies painted a clear socio-demographic and psychological picture of voters (and occasionally of participants in campaigns). In contrast to nonparticipants, participants in general had more money and education, were more interested in politics, more partisan, more efficacious, more likely to be men, more involved in organizations, and more rooted in their community. Some, including Rokkan, also paid close attention to the relationship between political behavior, including participation, and the citizen's position in the social cleavage structure.

Milbrath summarized the findings to date in 1965. He included political support as participation as well as electoral activities beyond voting. He promoted the influential organizing idea that participation lay on a hierarchical scale – there was a ladder of activities, with the easiest at the bottom and the most difficult at the top. 'Persons who engage in the topmost behaviors are very likely to perform those lower in rank also' (Milbrath, 1965, pp. 17–18). Given the emphasis on electoral activities and given the frame created by the ladder concept, levels of participation in the United States were perceived as low.

Large-Scale Cross-National Studies

Interest in democratic stability prompted cross-national projects that took political participation as an important variable. For Harry Eckstein, participation provided the link upwards from subordinates to superordinates (Eckstein and Gurr, 1975, pp. 60–67). For Almond and Verba in *The Civic Culture* (1963), the participatory behavior of citizens in a country was one important component in characterizing their political culture, but they were just as interested in attitudes and beliefs about hypothetical behavior as in activity. Nonetheless, the data, collected in 1959 and 1960 in five countries (the United States, Mexico, Italy, West Germany, and Great Britain) provided the first major database used for cross-national comparisons of political participation, especially beyond voting turnout. Some of these analyses contributed the important conclusions that persons involved in organizations participate more in politics and that societies with denser organizational structures exhibit higher levels of participation.

Within the decade (1966–71) Verba was in the field again, with an international team of collaborators, studying political activity. Surveys were completed in the United States, Japan, Austria, the Netherlands, India, Nigeria, and the former Yugoslavia. Some of the first products of this research (e.g., Verba and Nie, 1972) overturned the conception of participation as a hierarchy of electoral activities. Instead, participation was expanded to include nonelectoral activities and reconceptualized as modes of activity in any one or more of which individuals might specialize. Although often these are positively correlated, meaning that a participant in one is more likely to take part in others than a randomly selected person, many people nonetheless partake in one or some to the exclusion of other forms of participation. In particular, substantial numbers of people who avoided electoral politics did engage in nonpartisan participation, such as involvement with community groups.

As reported in Verba and Nie (1972) and Verba et al. (1978), as well as other publications from the project, wealth and education were reaffirmed as important predictors of participation. But the main theoretical point is that the strength of that relationship varies across societies as a function of the strength of other, 'group,' resources. Where these are strong, such as in countries with strong political cleavages tied to ascriptive characteristics, or with sociological or occupational segments with strong political leadership, the relationship of socioeconomic status (SES) to participation was relatively weak. Certain well-off segments of the population were 'inhibited' from participation while other, possibly disadvantaged, segments were 'mobilized,' thereby together attenuating the relationship between SES and participation. While others had noted similar phenomena, the finding now had wide cross-national grounding.

The Verba and coworkers' studies deliberately ignored political protest, that is, participation in activities outside accepted conventional norms, including some that are illegal. This omission seemed unfortunate by the 1970s in light of the frequency of real-world protest. Out of the study of revolution and political violence (*see* Revolution) came renewed interest in relative deprivation. But many protest activities are not violent (*see* Political Protest and Civil Disobedience).

A group of European and American scholars launched the Political Action project, a cross-national study focused on protest. They conducted surveys in the United States, West Germany, the Netherlands, Great Britain, and Austria in 1973–74, in Italy, Switzerland, and Finland 2 years later, and a second wave in the first three countries in 1979–80. The results appeared in *Political Action* (Barnes et al., 1979), *Continuities in Political Action* (Jennings et al., 1989), and other publications. One objective of this research was to understand the relationship between protest and conventional participation. The Political Action project clearly showed that enough persons who participated in conventional politics were adding protest to their 'action repertory' to conclude that conventional and protest participation were complements rather than substitutes. The Political Action studies differed from their predecessors in showing that variations in values predict both who will be active and the form of their activity. Specifically, persons with postmaterialist values are more active and more likely to protest than are materialists. Interpretation of the results is hampered slightly by the inclusion of respondents' hypothetical willingness to protest in some of the measures of protest activity.

Other scholars investigated the effect of political institutions on participation. In particular, they showed that cross-national variations in voter turnout rates reflect differences in electoral systems, party competitiveness, registration systems, government structure, and requirements to vote.

Attention to participation in organizations shades into studies of social movements. Where a political scientist sees a participant in a voluntary organization addressing a specific problem (and thus somehow engaged in the communal mode of participation), a sociologist sees someone active in a social movement. The latter have produced another extensive, related literature.

Approaches and/or theories from these cross-national projects have been influential in many country-specific studies of participation. These studies have contributed much that is new, but their conclusions have also tended to support the theories developed in the large projects.

Mobilization as a Predictor of Participation, Not a Type, and the CVM

The next major theoretical development in the study of participation involved incorporation of the recognition that people are more likely to participate when they are asked to do so (i.e., when they are 'recruited' or 'mobilized') and, moreover, that mobilization follows systematic patterns. Rosenstone and Hansen (1993) developed this idea in their study of participation in the United States from 1956 to 1990, claiming that a decline in mobilization over that period accounts in large part for the observed decline in participation.

Verba et al. (1995) use the related concept of 'recruitment' cross-sectionally in their study of political participation in the United States based on a 1989–90 survey. It is the third component of the CVM; the first two are 'resources' and 'engagement.' They argue that higher levels of any of these factors lead to greater participation – people participate in politics because they can, because they want to, and because someone asks.

'Resources' are most readily measured by income and education, but these serve as proxies for more fundamental measures. The most interesting components of resources are the 'civic skills,' operationalized by Verba et al. (1995) as writing a letter, making a speech, and attending or planning a meeting where decisions are made in one or more nonpolitical settings, such as on the job, at church, or in a voluntary association. Civic skills turn out to explain the long-observed association between organization membership and participation. 'Engagement' includes interest, efficacy, political information, and partisan attachment, and also specific issue or ideological concerns. Note the connection between this part of the model and the finding that post-materialists are more participatory. 'Recruitment' includes both requests from individuals and those from persons in authority (e.g., on the job, at church, or in an organization). This latter route provides one path by which group resources operate.

People with greater wealth and education in general have more resources, are more engaged, and are more likely to be recruited, so overall the relationship between socioeconomic status and participation is positive. The CVM model provides a fuller understanding however of why the relationship holds. Moreover, were it applied cross-nationally, it would point to components that need measuring. For example, churches play a role in the United States that is not likely to be replicated elsewhere.

Cost and benefit analyses inspired by rational actor models influence much contemporary work on participation, including that of Rosenstone and Hansen (1993) and Verba et al. (1995).

Many of the factors that lead to high levels of political participation are associated with high levels of social capital (*see* Social Capital) notably including substantial organizational involvement. Since social capital is also measured with political participation, the relationship among the concepts and the phenomena need more attention.

Conceptual Issues in Research on Political Participation

Participation Outside Advanced Democratic Countries

Most of the research discussed above has focused on economically advanced democratic countries, with the occasional addition of other research sites. The restriction to democratic countries reflects the particular role of political participation in a democracy. Participation provides the means by which people control their government, most decisively so in elections which determine who rules. The unique power of the vote to change rulers provides the force for most of the other modes of participation. Campaigning, expressions of opinion, community organizing, and other actions command attention in part because ultimately the opposition can win an election.

In an authoritarian regime, the electoral connection no longer exists. Nonetheless, there is still political participation. Although the people no longer select the rulers, the rulers still need to keep the population reasonably satisfied to forestall revolt, and, to do so, they need information on the people's preferences, and they need to respond to discontent. Several very interesting studies have examined participation in authoritarian regimes, such as Friedgut's study of the USSR (1979) and the work by Shi (1997) on China.

In economically less-developed countries, one frequently finds that government institutions are also less well developed, that the associational networks are weak, or that loyalties to local groups outweigh those to governmental institutions. In these circumstances, much political participation may consist of informal involvement in the local arena or in traditional institutions (see, for example, Dietz, 1998).

Issues of cross-national and cross-cultural comparability loom large in all studies of participation, but they are especially salient for research in nondemocratic or less advanced countries. One must rethink what counts as 'political' in these contexts in light of the institutional situation. For example, some of these studies led to the suggestion that participation includes activity directed toward altering the implementation of policy, rather than just its formulation, or that bribery is an important mode. Certain actions that are nominally the same can serve very different functions in differing contexts. For example, 'voting' may just show regime support in one country but select a government in another. The independent variables of importance also vary. For example, because of the particular circumstances in China, 'education' does not usefully measure resources there (Shi, 1997, pp. 145–148). In many countries, other institutions are likely to play the role of churches in the United States as a source of civic skills.

Matters become more complex when an authoritarian regime democratizes. Many current studies examine participation in Eastern Europe and the republics of the former Soviet Union. With the abrupt changes in regime, the process of political socialization (*see* Politics and Socialization) will probably also change, providing good conditions in which to observe the effect of political attitudes on participation.

Leadership

If people participate more when they have resources, are engaged, and are recruited, then elite action can significantly alter the level of participation by affecting engagement and recruitment. Political leaders provide resources to make participation easier (such as a babysitter, a ride to the polls, or information on what to support). Leaders contact people, directly or through proxies, asking them for action. Leaders can increase engagement by framing the public debate in a way that increases the stakes of political competition by communicating this message to their listeners.

The contemporary mass media plays a role very similar that of to leaders. They frame issues and strongly affect (at times, negatively) engagement and recruitment. However, their motivations differ from those of leaders as they seek attention rather than support, and their actions are not targeted.

The political world has many persons vying for power, each of whom needs large numbers of supporters to achieve power. Only some are successful in recruiting others and, as noted above, theory has not yet explained the circumstances of success. But political participation will increase when many are active and successful, and it will be higher than otherwise expected for persons who are targets of their efforts.

Editors' Note

The years following the publication of Uhlaner's essay above have witnessed renewed emphases on many topics in participation research. Four topics are:

1. What participation is – In relative terms, less emphasis has been placed on defining participation in general, and more emphasis has been given to newer activities within each major type (electoral, communal, protest), as well as to newer types of participation such as boycotting/buycotting as a newer protest activity, and political discussion and social media use as a newer participation type (see, e.g., Dalton, 2014, Chapter 3).
2. Has participation changed – For example, voting turnout has decreased but remains the most frequently performed electoral activity; signing petitions has increased and is the most frequently engaged in protest activity, with its frequency now similar to that of voting turnout in some countries; and communal activities occurring more or similarly often in the United States compared with other countries (see Dalton, 2014, Chapter 4; see also Attitudes, Political and Civic Culture; Political Protest and Civil Disobedience; and Voting: Turnout in this encyclopedia).
3. Who participates – Current research continues to focus on whether and if so, then why differences in electoral, communal, and protest activities have contracted or expanded between people who are less educated, ethnic-minority members, of lower socioeconomic status, and/or younger, and their counterparts (see Dalton, 2014, Chapter 4; Leighley and Nagler, 2013). With respect to younger people, there is now more focus on the effects of civic education, and of Internet and other social media uses, on their engagement in electoral, communal, or protest activities (see, e.g., Dalton, 2009; Milner, 2010; see also Generations: Political and Politics and Socialization in this encyclopedia).
4. How participation can/should be studied – This refers to the design of studies capable of providing the data necessary to test which of several alternative models provide(s), or whether a coherent, composite model produces, the best explanation(s) of electoral, communal, and/or protest participation. Notable models are cognitive engagement (information interest), civic voluntarism (resources mobilization), equity fairness (relative deprivation), general incentives (costs–benefits–norms), and social capital (networks trust) (for research reviews and test results, see, e.g., Clarke et al., 2004, Chapters 7 and 8; Whiteley et al., 2013, pp. 105–108).

Abstract

In its broadest sense political socialization refers to the content, processes, and dynamics of political learning across time and space. Related terms include civic education and citizenship training. The practice of political socialization is as old as political life. However, the term itself, and systematic research, did not emerge until the post-World War II period. An initial burst of scholarship in the 1960s and 1970s was followed by a prolonged decline. Interest revived during the 1990s, fueled in part by democratization movements around the world and, ironically, by concerns in established democracies about the declines in civic virtue among upcoming cohorts. The consequences of political socialization have been gauged in terms of its impact on the political character of individuals, the perpetuation of political cultures, and the functioning of political systems. Although most attention has been devoted to socialization in the pre-adult years, research in the area often merges into issues involving life cycle, generational, and historical effects. Survey research has been the most commonly employed methodology in the field. Longitudinal and cross-national research designs have been especially valuable in advancing the state of knowledge.

In its broadest sense political socialization refers to the content, processes, and dynamics of political learning across time and space. Related, more restricted terms include civic education and citizenship training. Because of the importance commonly attached to the consequences of early socialization, scholarship in this area has focused on the pre-adult years though not to the exclusion of later periods as well. Political socialization figures heavily in discussions of political culture, the relation of the individual to the political system, and political system stability and change. This article covers the major foci of the field, methodological approaches, and the field's evolution and development since the 1950s.

Major Topics and Questions

Some scholars, political scientists in particular, are concerned about the implications of political socialization for how political institutions function. Other scholars focus more on what socialization means for individuals and how they cope with their political environment.

Scholars have tended to borrow from other disciplines rather than developing original perspectives. Applications of social learning and cognitive growth theories predominate. Learning about politics occurs as a result of intentional and direct efforts as well as unintentional and indirect efforts.

The range extends from broad topics such as national identity and consensus political norms to narrower ones such as partisanship and issue preferences. The broader topics are especially important in terms of how political culture is preserved, while the narrower ones help explain individual level behavior and attitudes.

The 'agents of socialization' is one of the most explored topics, with the role of the family, schools, and political events receiving heaviest scrutiny. Complex research designs are often employed here so that the individuals being socialized can be matched up with the agents providing the socialization cues.

There are intracountry variations. Political socialization may proceed in different ways and generate different outcomes according to individual and contextual characteristics. Most attention has been paid to the role of social class, gender, race, region, religion, and birth cohort.

On the other hand cross-country variations exist. Commonalties based on individual developmental processes and differences based on institutional arrangements have been observed. Some of these conclusions are based on systematic, multicountry investigations whereas others are derived from a comparison of independent, one-country studies.

Although much emphasis has been placed on transitions from early childhood up through young adulthood, the study of political socialization increasingly is being viewed from a lifelong perspective in order to comprehend the residues of earlier socialization as well as the impact of adult life stage transitions. For many nonconsensus political beliefs and practices the formative years appear to be young adulthood, after which beliefs and practices tend to solidify. For beliefs and values of a more integral and widely shared nature, the formative years occur earlier.

Of interest to a wide range of scholars, generational and historical effects may reflect either gradual changes in the social composition of succeeding cohorts or sharper discontinuities due to secular events. Rising education levels and affluence exemplify generational effects due to social composition. Wars, depressions, revolutions, and student protest movements are examples of more abrupt, event-driven effects.

Methodology

The majority of the literature rests on a foundation of empirical methodology. Attention has focused more on individuals than on institutions and systems as units of analysis.

There are various modes of data gathering. Surveys of probability and nonprobability samples compose the major

mode. Three variants have been used. One consists of self-administered questionnaires of elementary and secondary school students. The use of such instruments for young children has been questioned. A second variant consists of personal interviews, either face to face or by telephone. Some of these surveys employ a structured format while others are more semi-structured. Investigators using either mode typically employ statistical analysis. Other modes of data collection include intensive interviews, sometimes combined with participant observation and projective techniques, with a small number of subjects (Coles, 1987). Analysis in this instance is usually qualitative in nature. Although not typically classified under the heading of political socialization, analytic biographies of political figures – employing a variety of data sources—also constitute a mode of data gathering. Studies based on experiments are relatively rare.

Most investigations are cross-sectional, that is, the subjects were studied only once. However, a few over-time studies of the same individuals exist, thereby enabling more insight into developmental patterns. Some studies stretch from pre to full adulthood and involve either special populations or more general ones. Other longitudinal projects, especially those assessing the impact of educational institutions and political events, cover a shorter period of time.

Replicated surveys of the same populations provide historical trend data. Longitudinal studies of pre-adult populations are now available in a number of countries via national and international archives. Similarly, replicated surveys of adult birth cohorts are widely available. These surveys facilitate analyses devoted to assessing the probable impact of preadult experiences as cohorts age.

Initial Development and Ascendance of the Field

The phenomenon of political socialization has a long history. The preparation of individuals for their roles in the political world is as old as political life itself. Both political authorities and ordinary citizens have been subject to the practices and outcomes of socialization regardless of political regime type. By contrast, the systematic study of political socialization has a relatively short history. Around the turn of the twentieth century educators in the United States conducted studies of school children that included choices of exemplars, national figures most admired by the children (Greenstein, 1965). These 'surveys' and occasional other investigations in a variety of settings marked the first empirical studies of what would later be called political socialization.

It was not until the post- World War II era that more sustained, disciplined research emerged. The term itself surfaced in the mid-1950s. By the early 1960s the label had achieved wide academic currency among political scientists in the United States and quickly spread to other western countries. Early work in the Unites States, the initial center of the empirical investigations, focused on pre-adolescents and emphasized the positive and relatively benign processes and outcomes of political socialization. Although more realistic perceptions and understandings set in with advancing age and cognitive development, the overall effect was viewed as salutary both for the successful functioning of the political system and the citizenry (Easton and Dennis, 1969).

Following in the wake of these pioneering studies came a flood of projects in the United States and elsewhere. These inquiries tended to elaborate upon, modify, and in some instances to reject the conclusions of the earlier work. Variations according to social class, race, and location were identified. Political institutions conditioned the content, processes, and outcomes in fundamental ways. Considerable attention was devoted to the agents of socialization. Although the family appeared to be the key agent, it became clear that many other forces—including individuals themselves—also contribute to the formation and maintenance of political orientations. In general the more concrete, affect-laden, and reinforced the attribute in question, the more likely it was to be reproduced in the person being socialized and to persist over time.

Waning Interest

Scholarly inquiry in this area began to decline after the mid-1970s, especially in the United States. What had been a bull market turned bearish. Two factors appeared to be at work beyond the fading effect often associated with scholarly trends. One source lay in the dwindling novelty of studying school children. Political scientists in particular were accustomed to dealing with the 'real world' of politics, one occupied and ruled by adults. A second likely source rested in the appearance of youth movements throughout much of the western world in the late 1960s and early 1970s. This development not only shifted attention away from pre-adults but also appeared to undermine the proposition that the trusting orientations observed in many of the earlier studies would persist over time. Indeed, the question of persistence posed a serious threat to the field.

Ironically, even as fresh research efforts tailed off, the concept and the term itself became embedded in any number of subfields, including public opinion, electoral behavior, the politics of race and gender, political culture, and regime stability. Political socialization came to be assumed, rather than observed. Still, research continued on in a number of countries (Percheron, 1993; Ichilov, 1990) and longitudinal studies began to appear (Alwin et al., 1991; Jennings and Niemi, 1981).

Resurgence and Future Prospects

After a prolonged lull, scholarly inquiry began to increase in the 1990s and has continued onward. Three developments helped lead to a resurgence of interest. One development was the crumbling of the Soviet Union and the appearance of transitional regimes and new democracies around the globe. These changes generated numerous surveys of adults that emphasize generational differences and studies of how and with what effect pre-adults are being socialized under the new regimes (e.g., Flanagan and Sherrod, 1998). New, large-scale immigration patterns also presented opportunities for studies of adult resocialization. Thus, dramatic events in the political world have provided a natural laboratory for examining the processes

and outcomes of political socialization. A second development springs from the decline in social capital and civic virtue among upcoming cohorts said to characterize most Western countries. In an effort to understand what is happening and to propose possible solutions, a variety of institutions and scholars have turned to the question of education and training of the young. National and cross-national assessments dealing with the character and impact of curriculum and school characteristics are being employed (Smith, 1999). Much of this work is being carried out under the banner of civic education inquiries (Torney-Purta et al., 2001).

A third development consists of renewed interest in the question of persistence and the dynamics of learning. Results from the long-term panel studies form part of this renewal as do the shorter-term studies of children and adolescents. The accumulation of replicated surveys as represented by such projects as national election studies, the General Social Surveys, and the Eurobarometer Surveys are also relevant because they permit the tracing of birth cohorts over extended periods of time. In doing so, they enable informed interpretations drawing upon the conditions under which pre-adult socialization occurred and how these cohorts respond to later developments. These new developments augur well for continued scholarly inquiry. At the same time, the prospects remain bleak with respect to the study of young children, a major focus of the early research efforts.

Editor's Note

M. Kent Jennings is one of the 'founding fathers' of political socialization research and theory and among the first to recognize that if we seek to understand the political views and behaviors of adults, we need to start by looking at how political thinking is formed in childhood. Jennings' earliest publication on the topic dates to 1968 ("The Transmission of Political Values from Parent to Child" (with Richard G. Niemi), American Political Science Review, 62 (March, 1968), 169–184.) His article on the topic in the first edition of the Encyclopedia is reproduced here as a legacy entry.

Abstract

This article describes the noncooperative game-theoretic approach to studying political phenomena, using examples to illustrate the various concepts and moving parts. It examines the ability of this approach to generate conclusions about the influence of different political institutions on policy outcomes. This approach is put in the context of earlier results from the cooperative game-theoretic approach, for example the median voter theorem and the chaos theorems.

Positive theories of politics provide explanations for why political phenomena occur in the manner that they do. Examples of such phenomena include which parties or candidates are elected at certain times, what policies legislative bodies adopt, and when and how wars are fought between countries. Formal models complement these explanations by using the language and analysis of mathematics to derive the phenomena as necessary consequences of certain sets of underlying factors. As with mathematical models in other disciplines, the main advantage of such an approach is twofold: to give an unambiguous representation of the relevant moving parts of a theory (the clarity of the argument) and to enforce a logical coherence on a theory (the consistency of the argument). The main drawback is found in the required simplification of the phenomena down to a manageable number of moving parts, and the subsequent possibility of simplifying away the very essence of the problem.

The Basic Structure

Most formal models of politics fall in the category of rational choice where the presumption is that observed outcomes are the result of decisions made by a certain relevant set of individuals. These could be voters and candidates in the first example above, elected representatives and appointed ministers in the second, or heads of state in the third. The general behavioral postulate is that individuals attempt to influence the outcome in a manner reflecting their preferences (tastes, values, etc.) over the set of possible outcomes. For instance, in selecting campaign platforms, a candidate who only cares about winning the current election might look to adopt policies appealing to the greatest number of voters; conversely, a candidate who cares intrinsically about the policies to be implemented might shy away from politically popular but personally unpalatable alternatives. Whatever their specific form, individuals' preferences are taken to be primitives of the model, and so are held fixed throughout the analytic determination of an outcome. However, different specifications of preferences can give rise to different outcomes. Indeed, to the extent the predicted outcome varies with changes in the underlying individual preferences, one has a potential explanation for any variation in observed outcomes as being due to variation in these preferences. The extent to which these preferences can themselves be modeled as functions of observable parameters, such as wealth or legislative seniority, permits one to generate a theoretical relationship between these parameters and observable political outcomes as well.

The influence of preferences on outcomes occurs through the choices the individuals make. The most common assumption is that each individual's choice is optimal with respect to their preferences, for example, in the above scenario the candidate selects a vote-maximizing policy. This optimality assumption may be far from a realistic representation of individual decision-making, implying as it does that individuals can effortlessly solve what are at times relatively difficult mathematical problems. However, assuming otherwise typically requires the presence of auxiliary factors (for instance, decision costs) to rationalize *non*-optimizing behavior, factors which, while reasonable, tend to create additional complications in the model. Also the optimality assumption allows one to import existing results from optimization theory to aid in the analysis.

As seen in the examples above, most formal models of politics involve more than one individual, and so this individual level of optimization often takes place within the confines of non-cooperative game theory. Such models explicitly describe the interaction among the individuals that ultimately produces a collective decision. This description begins with a 'game form' consisting of (1) the set of strategies available to each individual, and (2) the specification of which outcome occurs when a given profile of strategies is chosen (with each profile consisting of one strategy per individual). Continuing with the electoral setting, one example of a game form is where the set of strategies for a candidate is equal to the set of available policies, a voter's strategy describes which candidate to vote for based on the candidates' chosen policies, and an outcome, consisting of who wins the election and with what policy, is determined by the candidate receiving the most votes. The remaining piece of the puzzle then is the derivation of the individuals' strategies, with the fundamental concept being that of the 'Nash equilibrium (Nash, 1950a, b; 1951).' Note that, even assuming all individuals have well-defined preferences over the set of outcomes, the notion of optimality in this multiperson environment is necessarily conditional, as an individual's best choice of strategy may depend nontrivially on the strategy choices by the other individuals. For instance, in the electoral game above, the location of

a candidate's optimal policy may depend on the voters' behavior as well as the policies endorsed by rivals. A Nash equilibrium is a profile of strategies wherein each individual's strategy is optimal, given the strategies of the others, that is, conditional on the choices by the other individuals, no one individual has an incentive to alter her choice. A Nash equilibrium outcome is thus a collective decision consistent with individually optimal behavior and constitutes the basic object of analysis in any noncooperative model. (In certain game forms, some Nash equilibria are inherently more plausible than others and so refinements of Nash equilibria, such as subgame perfection, are used.)

As with the choice of preferences, the choice of game form is in the hands of the modeler. This choice may be influenced by observable features of the political phenomenon in question, as in the above electoral example. In such situations, there will invariably be a trade-off between making the game form descriptively accurate and keeping the game form analytically tractable. Thus while the electoral rule may easily be incorporated, simplifying the campaign stage of the process to a single choice of policy, thereby avoiding the complexities found in actual elections, may be necessary to guarantee the existence of and to solve for equilibrium outcomes. At other times, there may not exist any such observable features to leverage, an example of which would be when two heads of state are bargaining over land and other resources in the shadow of war. Here one would be hard-pressed to assert that the unstructured negotiations taking place can be definitively captured in any one particular game form. Hence descriptive accuracy is not an issue, and the modeler is relatively unconstrained in the search for a 'good' game form, that is, a game form capable of generating new and valuable insights into the political phenomenon in question.

Yet to the extent that the game form incorporates observable features of the political process and that the equilibrium outcomes vary with these features, one has a second source of variation in outcomes above and beyond changes in preferences, namely, changes in the political process. For instance, the equilibrium outcomes under the above plurality electoral rule may differ from those associated with a run-off rule (where, if no candidate receives a majority of the votes, the two candidates receiving the highest number of votes are paired in a second election, in which majority rule determines the winner) even if the candidates' and voters' preferences are held fixed. This allows one to make statements about the degree to which differences in observed collective choices are due to differences in preferences, or to differences in political institutions. More ambitiously, this type of comparative institutional analysis can be used to predict the effect changes in existing political institutions will have on collective outcomes.

An Alternative Approach

While noncooperative game theory has tended to dominate the modeling landscape in recent years, much of the early formal work employed the techniques of cooperative game theory. Rather than explicitly modeling outcomes as the aggregation of individual decisions, under this approach one looks for outcomes that are stable in some sense, with this 'sense' implicitly characterizing the (unmodeled) underlying strategic interaction. Given the normative appeal and frequent use of majoritarian-based political procedures, the focus was primarily on identifying outcomes which are majority-preferred to all others in pair-wise comparisons. Such an outcome would then be immune to changes proposed by any majority coalition, whereas all other outcomes would not.

It turns out that a majority-stable outcome necessarily exists in certain environments, the most compelling being when the collective choice concerns the selection of a single number. For example, suppose the issue before a legislature is the size of the nation's military budget, the set of possible outcomes can be taken to be the set of nonnegative real numbers. Suppose further that the legislators have 'single-peaked' preferences: each has some best number, and the value to them of the outcome falls as one moves away from this best number. Then a stable outcome will exist and, if the number of individuals is odd, will be unique and equal to the median of these best numbers. This 'median voter theorem' has been at the core of numerous and varied empirical studies of collective choice, from local school budgets in the United States to European Union decision-making. Its comparative advantage as a formal model is obviously its parsimony, requiring as it does only a description of how individual preferences over outcomes are related to any underlying parameters of interest (e.g., household income in the local school budget case). Further, by imposing additional assumptions on preferences, one finds that the median voter's preferences coincide with those of the majority over the entire set of outcomes, implying that the median voter is in a literal sense representative of the collective as a whole. The benefits from this result accrue principally to the noncooperative modeler: suddenly a one-dimensional model of the interaction between the US President and the 435 members of the US House of Representatives over the size of the military budget, with majority rule dictating the decision-making among the latter, can be simplified to a two-person interaction between the President and the median member of the House.

The main shortcoming of the median voter theorem of course is its restriction on the set of outcomes to a single dimension. In certain situations this is benign, as in the above example when the policy choice in question consists of selecting the military budget. However, a policy choice consisting of the distribution of this budget across more than two groups is inherently a multidimensional problem and the conclusions about majority rule for multidimensional problems, relative to their single-dimensional cousins, could hardly be more dramatic. In particular, for most descriptions of preferences, no majority-stable outcome exists (where 'most' has a mathematically precise definition in this setting). As an example of such non-existence, suppose in the above scenario that each legislator cares only about how much their favorite group receives, with one-third of the legislators associated with each of three groups. Then for any distribution of the budget, the legislators for two groups (which together constitute a majority) prefer to take away any amount going to the third group and re-distribute it amongst themselves, thereby guaranteeing that no distribution is majority-stable. Furthermore, when no stable outcome exists, not only is there no representative voter but in fact one can construct majority

preference cycles throughout the policy space (i.e., policy *a* is majority-preferred to policy *b*, which is majority preferred to policy *c*, which … which is majority-preferred to policy *z*, which is majority-preferred to policy *a*). Thus when majority rule breaks down, it breaks down completely. Subsequent research has shown that these negative conclusions continue to hold, to a greater or lesser degree, for most non-majoritarian rules as well.

As with the median voter theorem, it is difficult to overstate the impact these 'chaos theorems' have had on the formal modeling of politics. Clearly, in a multi-dimensional world, the modeler has lost the analytic shortcut of representing a collective's decision-making as being governed by a single individual (or, at least, the logical rationale for doing so). More importantly, the theorems gave rise to a new-found appreciation for political institutions, such as committee systems, restrictive voting rules, and the like as key elements in the determination of collective outcomes. Indeed, such institutions are often depicted as necessary ingredients in any multidimensional model of politics, in that, but for such institutions, collective decision-making would fall prey to the inevitable onslaught of cycling and chaos. This interpretation, while quite popular, appears inconsistent with the central tenet of formal modeling, that of equilibrium analysis, as the chaos theorems are properly seen as nonequilibrium results. Put differently, these theorems do not predict that (as commonly phrased) 'anything can happen,' for as nonequilibrium results they do not predict anything at all. Rather, they demonstrate the impossibility of any general theory of collective behavior based solely on the (majority) aggregation of preferences, and hence the necessity of being more explicit about the decision-making process so as to provide the analytical traction required to formulate a well-posed model. From this perspective, the lesson to be learned from the chaos theorems is one for the modeler of collective decision-making, rather than as one about collective decision-making itself.

Editor's Note

Especially influential has been since then the work of E.Ostrom(1990; 1998; 2005) ; Ostrom/Gardner/Valker, 1994; Dietz/Ostrom/Stern, 2003, She analyzed the functioning of institutions from a rational choice and game theoretical point of view. Starting with the tragedy of the commons (Hardin, 1968) which has been a major concept in environmental research and policy discussions. One assumes that a common pool exists, which can be utilized by a lot of persons. This is true for example for the pacific ocean or the atlantic ocean from which many nations harvest fish. Overfishing has been taken place and may lead finally to the destruction of the resources. The central dilemma is as follows. If one nation stops to circumvent the destruction of the resources andtheothers however still continue, destruction goes on. A lot of research has been performed in the last thirty decades to clarify the conditions under which destruction takes place or constructive solutions are found. This stream of research has now combined mathematical models, laboratory experiments, field studies and case studies. Such a mixed method approach has become more frequently also in other applications.

Additionally game theory became a much more visible place in a lot of doctoral programs especially in the United States but also in the Netherlands, Great Britain, Germany and Japan.

Furthermore in the large summer schools from ICPR, ECPR and in the Essex Summer School game theory courses are regularly offered. Several general introductions to game theory and its application to political science have been now published (Austen-Smith/Banks, 1998; McCarthy/Meirowitz, 2007; Gates/Humes, 1997).

Pooled Cross-Sectional and Time Series Analyses, in Political Science

Ellen M Key, Appalachian State University, Boone, NC, USA
Matthew J Lebo, Stony Brook University, Stony Brook, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Time can either be treated as a nuisance or as a substantively interesting variable across a variety of political science subfields and a wide array of research questions. The popularity of studying political phenomena over time has increased over the past 40 years. Encompassing any study where data are collected at multiple points in time, time series analysis includes studies of duration, event counts, (pseudo-)panels, repeated cross-sections, pooled cross-sections, and studies of volatility. Beginning with a discussion of the development and integration of 'long' time series methodology in the political science literature, we also briefly discuss other types of time series. We conclude with some suggestions for future research.

Introduction

While most empirical analyses in political science study cross-sectional units, the use of political data measured over time has become increasingly popular over the past 40 years. The broad category of political time series would include any study where data are collected at more than one point in time. It contains many types of analysis including longer time series, event counts, studies of volatility, duration analysis, forecasts, pooled cross-sectional time series (PCSTS), panel models, pseudo-panels, and repeated cross-sectional analyses. This article begins with a discussion of 'long' time series methods and the integration and development of these approaches into the empirical literature in political science. Following that is a brief discussion of other types of time series.

There are many ways that time can be a factor in collecting and analyzing political data. The most prevalent example is the use of a variable collected at multiple points in time. Such a variable, denoted Y_t, could be the percent of samples giving a particular answer on identical survey measures at different points in time like monthly presidential approval (e.g., Mueller, 1970), the actions of one country toward another within multiple discrete time periods like the data collected by the Kansas Events Data System (e.g., Schrodt and Gerner, 1994), a measure of government actions or performance that is collected at regular intervals such as the percent of times a president wins his battles with Congress (e.g., Lebo and O'Geen, 2011), or one of the countless other examples.

Studying a political variable over time offers many advantages. To begin, the study of political dynamics is itself interesting – studying important political phenomena over time is certainly as promising as examining variation across units fixed in time. The movement of variables such as macropartisanship (MacKuen et al., 1989) and the gender gap (Box-Steffensmeier et al., 2004), for example, tell us a great deal about the long-term movement of the electorate and make important complements to cross-sectional studies. (The choice of the level of analysis is critical when beginning any project and the appropriate level of analysis depends on the research question. If it is an atomistic question about the behavior of individuals, then analysis should be conducted at the individual level. If, however, the question is about how the citizenry, electorate, or economy moves as a whole, then macroanalysis is the most appropriate.)

The value of aggregate-level studies has been demonstrated particularly well in the economic voting literature. As Erikson, MacKuen, and Stimson note "elections are won and lost in the aggregate. And the aggregate moves at the margin; a few people doing this or that systematically produces big, sometimes shocking, aggregate effects" (2002: xix). Although Converse (1964), Campbell et al. (1960), and others find the average citizen to show little ideological constraint, the degree of constraint varies throughout the population. The well informed are more likely to have stable opinions over time and the public as a whole is responsive to social, political, and economic change because opinion averages over the well and ill informed (Kinder, 2006; Page and Shapiro, 1992). In fact, it is these more informed citizens who contribute disproportionately to movement in the aggregate. Ill-informed citizens cancel each other out (Erikson et al., 2000). Although at the individual level individuals do not appear to have mastered complex political and economic ideas, in the aggregate they do appear to have done so. (Moreover, individual-level data is plagued with problems such as response bias and measurement error, problems which are diminished when responses are aggregated (Kramer, 1983).)

Thus, time series analysis offers a useful lens into political phenomena and the method has become prevalent as a research tool. **Figure 1** presents a count of the number of articles mentioning 'time series' in the *American Political Science Review*, *American Journal of Political Science*, *Journal of Politics*, and *Political Analysis* from 1970 to 2012. From a handful of articles in the early 1970s, there has been a steady increase to around 70 articles in recent years.

The increasing popularity of time series is in large part due to increased data availability. Economists have had over half a century of rich temporal data to draw upon, but analogous data were not available for political scientists until the past few decades. Systematic data collection programs have led to the increased availability of long t time series focusing on political phenomena. Hand in hand with the growing body of data are the development of research methods that allow the study of complex dynamic relationships.

Figure 1 Time series articles per year, 1970–2012.

Advantage and Pitfalls of Time Series Analysis

Studying the evolution of data over time allows insights that prove more difficult or impossible for cross-sectional data. For one, studying just the univariate characteristics of a variable can be extremely useful. Knowing the way in which a time series's value depends on its past values means that we can make forecasts of the series's values ignorant of other predictors (Hibbs, 1977). Studying incidents of terrorism (e.g., Enders and Sandler, 2005) or the swings of the electoral pendulum (e.g., Lebo and Norpoth, 2011; Norpoth, 1996), for example, can lead to useful forecasts even without incorporating independent variables. The forecasting of elections may add independent variables to a model but will usually rely as well on identifying the pattern in a small number of data points and extrapolating to the next one. Such exercises have been an entertaining field roughly since the 1992 American presidential election (Campbell, 1992).

The ordering of observations also makes it possible to stretch beyond correlation and catch glimpses of causation. For example, if by incorporating past values of X_t we can improve our the predictions of Y_t beyond what the history of Y_t would predict, we can say that X_t 'Granger causes' Y_t (Granger, 1969; Freeman, 1983). Thus, researchers are able to study questions such as whether the economy affects economic judgments or vice versa (De Boef and Kellstedt, 2004). Multiple equation setups such as vector autoregression (VAR, Freeman et al., 1989; Sims, 1980), near-VARS (Enders, 2004), and seemingly unrelated regressions (e.g., Lebo et al., 2007) allow the study of complex dynamic relationships that might include reciprocal causality and feedback. In this way, time series analysis is protected from some critiques of observational studies developed in recent years as political scientists are paying more attention to the logic of causal inference.

But the ordering of observations also creates a range of complications. Much of the statistical theory is concerned with random samples of independent observations, but in time series, successive observations are usually not independent. In a cross-sectional survey, for example, the answers respondent #100 gives are unlikely to have any special relationship with the responses of person #101. The ordering of the observations is simply random. In time series, on the other hand, the value of a variable at time-point 100 is likely to be highly correlated with its value at time-point 101. This is a form of autocorrelation – cases nearer to each other in time will be more highly correlated with each other than observations more distant. This means that the statistical notion of identically and independently distributed observations is unlikely to hold with time series data.

This temporal dependence also means that popular techniques like ordinary least squares (OLS) encounter serious problems with time series data. This has led to an entirely separate branch of statistical methods (e.g., Box and Pierce, 1970; Box and Jenkins, 1976). Time series analysis generally takes careful steps to separate the two components of a time series: the deterministic and the stochastic. The deterministic portion is the part that is predictable based on past values and the stochastic component is what remains and might be partially explained by independent variables. Techniques like the Box and Jenkins (1976) transfer function approach build multivariate models only after first modeling how each variable depends upon its own past history (McCleary and Hay, 1980).

Political Science and Time Series Analysis

The development of time series analysis within political science has been very much aligned with popularity functions beginning in the early 1970s with the work of Mueller (1970, 1973) who studied the decay of job approval across the president's term. Mueller modeled a linear decline in popularity due to the fragmentation of a 'coalition of minorities' created during the presidential term. Subsequent research by

others focused on the appropriate way to model approval as a time series. Stimson (1976) argued the effect was quadratic, rather than linear, with approval declining after the start of the term but then experiencing an uptick near the end of the term. He attributed the initial decline to the disillusionment of uninformed citizens after the buildup of expectations surrounding the election. Similarly, the subsequent increase in approval at the end of the term is a result of increasing expectations leading into the next election. Kernell (1978) argued approval does not decline solely due to time, but rather the ebb and flow of approval can be attributed to political and economic events properly specified. Likewise, Monroe (1978) criticized Stimson for misspecifying the effects of the economy by using a time counter rather than objective economic indicators and actual expenditures.

Indeed, multivariate time series methods have developed in large part in tandem with models of economic voting. The compilation of monthly series of subjective economic evaluations – Gallup data in Britain and the Index of Consumer Sentiment in the United States – led to long debates regarding identifying the most important economic factors to voter decisions. On one hand, Key (1966) claims that voters punish or reward incumbents for the state of their pocketbooks, a view that supports personal retrospective evaluations. In contrast, Sanders (1993) used personal expectations as a key to forecasting the surprise Conservative victory in the 1992 British General Election. Looking at the effects of macroopinion on the national economy, MacKuen et al. (1992) see the electorate as forward-looking 'bankers' rather than retrospectively focused 'peasants' (Norpoth, 1996). Importantly, Clarke and Stewart (1994) pushed the discipline forward by sorting through the methodological issues in the data at issue. The concept of unit roots was long studied in economics but had not made its way to political science. When Clarke and Stewart (1994) allowed for and tested this possibility they found elements of truth in both theoretical approaches – the electorate is both prospective and retrospective. Further, Clarke and Stewart (1994) introduce the concepts of cointegration and error correction (Engle and Granger, 1987) to political scientists.

Series are cointegrated if there exists a mean-stationary linear combination of the variables. This expansion of the methodological toolkit allows the study of long-run equilibrium relationship between variables that would be obscured by traditional differencing techniques (see e.g., Clarke and Stewart, 1995; Clarke et al., 1998; Clarke and Lebo, 2003). As shocks drive cointegrated series apart, an error correction mechanism can be used to capture how quickly the series return to equilibrium. Several political and economic variables are cointegrated. In their study of the South African economy, Dunne and Vougas (1999) found economic growth and military spending are cointegrated, showing the negative effect protracted military conflicts have on economic health. Noneconomic variables may also be cointegrated. For example, the norm of consensus on the Supreme Court eroded around the time of the New Deal. Calderia and Zorn (1998) show the rate of concurrences and dissents, which are cointegrated, are affected by the decline of this norm. Another set of noneconomic cointegrated series is prime minister popularity and governing party support in Great Britain (Clarke et al., 2000). In all, a variety of political variables are cointegrated and error correction mechanisms allow for the study of these complex relationships.

As in many areas of political methodology, the 1990s saw a boom of new methods and approaches to time series analysis. Aside from the expansion of tools, important work began studying the ways in which political data differed from the majority of economic time series. So many of the methods used by political science had simply been imported from work in economics without much thought regarding how the basic data generating processes between the fields might differ.

For example, Box-Steffensmeier and Smith (1996) showed the need for fractional integration methods, a small corner of econometric research, to be widely used with political data. Although series can be analyzed in level form – without transforming its values – if it is not mean-reverting the failure to account for this may result in spurious regressions where it is falsely concluded that a relationship exists between two factors.

One way to correct for this is to first difference the data, however this, too may be insufficient. While differencing the data provide significant improvement over the level-form analysis of nonstationary series, it may overcorrect by overdifferencing the data if the series is not truly a unit root, building in an moving average (MA) parameter that is not present in the data generating process. The best way to avoid overdifferencing while still making a series stationary is to fractionally difference the data. Fractional integration is theoretically motivated when heterogeneity at the individual level exists due to individual-level variation in the persistence of new information (Granger and Joyeux, 1980). Some individuals have long or perfect memory (or a strong autoregressive process) and others less so (Box-Steffensmeier and Smith, 1996). This heterogeneity at the individual level produces aggregate series that are neither stationary nor unit roots, but instead have a mix of properties. Several variables of interest to political scientists are fractionally integrated, including partisanship (Box-Steffensmeier and Smith, 1998) and presidential approval (Lebo et al., 2000). Autoregressive fractionally integrated moving average techniques allow for a series to have long, but not perfect memory. Shocks to series can persist but eventually be discounted over time.

Other Approaches to Time Series Research – Volatility, Time-Varying Parameters, and Dynamic Effects

There are multiple ways to trace the dynamics of a series or a system of series. Because the relationships studied by political scientists are extremely complex, there are many reciprocal relationships and feedback loops. One way to study the dynamic interrelationship between variables is to use an impulse response function (IRF). IRFs trace the cumulative effect of a shock to one variable as it moves its way through a VAR system (Sims, 1980). For example, Box-Steffensmeier and Smith (1996) use an IRF to determine the persistence of shocks to macropartisanship. These changes to the series decay slowly and persist the effect can be felt for years. Similar

patterns are evidenced in the Republican and Democratic series, indicating that macropartisanship does change on the scale of years rather than decades or months. IRFs have also been used to study political bureaucratic adoption (Wood and Waterman, 1993), presidential rhetoric and economic performance (Wood et al., 2005), and fatalities on Israeli–Palestinian relations (Jaeger and Paserman, 2005).

Another branch of analysis goes beyond studying how time series rise and fall and looks at changes in the volatility. Although variables are often assumed to have constant error variance across time, in reality many go through different periods of stability and volatility. Volatility clustering, first studied in the financial markets, refers to that phenomena that "[w]hen volatility is high, it is likely to remain high, and when it is low it is likely to remain low" (Engle, 2003). Autoregressive conditional heteroskedasticity (ARCH) and the generalized form (GARCH) allow for modeling the variance as well as the mean of a series. This has been used primarily to study volatility in popularity functions, e.g., Gronke and Brehm (2002), using a modified ARCH approach, found volatility in presidential approval to have increased over time. The effect of events on approval volatility, however, is conditional on the partisan identification of the respondent. Positive presidential events create cognitive dissonance in out-party identifiers, leading to increased volatility (Kriner and Schwartz, 2009). Mounting wartime casualties may even increase volatility among the president's most strident supporters, as was the case with Franklin Roosevelt and federal assistance recipients during World War II (Kriner, 2006). Just as one would expect volatility to be low among those most predisposed to support the president, one would also expect macropartisanship to be relatively stable over time. However, electoral cycles and waning party identification create periods of high volatility in aggregate partisan identification (Maestas, 1997). If periods of high volatility in either presidential popularity or macropartisanship were to coincide with an election, the outcome would be much more difficult to forecast.

Other lines of research are opened when one considers that the relationship between variables may change over time in interesting and predictable ways due to circumstances such as elections, recessions, wartime, or other factors. Three common ways to test for dynamic relationships between time series are moving windows, Kalman Filter, and dynamic conditional correlations (DCC, Lebo and Box-Steffensmeier, 2008). To use a moving window estimator design, the researcher first selects the size of the window (s), and runs a model using just the first s observations. The process is then repeated in an iterative fashion as the window moves across the data, using observations 2 to $s+1$, 3 to $s+2$, etc. After model estimation is complete, the correlation (or regression coefficients) provides insight into the changing nature of the relationship. Moving windows are useful when the time period being studied is shorter or if the researcher has strong expectations of when the relationship should change over time (e.g., presidential administrations). Moving windows have been used to study the relationship between international trade and the opportunistic timing of elections (Kayser, 2006), social spending and partisanship in OECD countries (Kwon and Potusson, 2010), and economic health's effect on policy liberalism (Ferguson et al., 2013).

The Kalman Filter is a recursive system that starts with some data, points 1 to s, and then adds more data iteratively (e.g., Bond et al., 2003). Unlike the moving window, past observations are not dropped out of the analysis as new observations are added. Eventually, the coefficients converge upon the estimate one would obtain if the relationship was time invariant. Thus, a Kalman Filter allows us to see the evolution of a coefficient over time. Stimson et al.'s (1995) model of policy responsiveness, dubbed 'dynamic representation,' was estimated using a Kalman Filter. As public opinion becomes more liberal, governmental institutions respond with more liberal policy outputs. Similarly, public opinion about the president's job performance, a factor so heavily colored by partisanship that it should have little explanatory power, affects the president's legislative success (Bond et al., 2003).

A relatively new technique for political researchers is the dynamic conditional correlation model developed by Engle (2002) and introduced to political science by Lebo and Box-Steffensmeier (2008). Building on multivariate-GARCH models, DCC models allow researchers to study the direction and strength of the relationship while taking into account the volatility in the times series. One can find periods of no correlation, as well as positive and negative correlation, between two or more series. Consumer sentiment and presidential approval, for example, are two series that have nonconstant correlation (Lebo and Box-Steffensmeier, 2008). The DCC method's ability to tell what a correlation is *now* shows that, over 30 years of data, the height of correlation between presidential approval and economic sentiment was during the 1992 presidential election – it was, in fact, 'the economy, stupid.' Wars and terrorist events have sometimes even produced negative correlations between economic and political assessments.

Event History Models

Many of the data that are of interest to political scientists denote change from one 'regime' to the next. Beyond just the transition from one state to another, the factors precipitating the change may also be of interest. This leads to research questions that are focused on the timing and change as well as the ultimate outcome. Event history models, also known as duration or survival models, have grown in popularity in the social science literature since the 1990s, culminating in the publication of Box-Steffensmeier and Jones' (2004) key book on the subject (see also Box-Steffensmeier and Jones, 1997).

Initially, the temporal structure of event data was treated as a nuisance, rather than being of substantive interest. As a result the temporal ordering was ignored and post hoc corrections were applied to correct for autocorrelation in the data. In the early 1990s, Bartels and Brady encouraged political scientists to incorporate more techniques specifically designed to analyze event history data (1993). Heeding their advice, researchers began to import methods from biostatistics to measure the 'risk' that an event would occur and the likelihood of an observation's 'survival' at the end of the study.

There are several problems inherent in analyzing event data. The data are always nonnegative, leading traditional estimation methods to return nonsensical predictions. Furthermore, survival at time t is conditional on the observation having not experienced the event by time $t-1$, so this dependence must be accounted for. Finally, there is the problem of censoring. At the end of the period of study, some observations at risk will not have experienced the event. This leads to biased estimates if not corrected.

This durational framework has been applied to a variety of political science subfields. King et al. (1990) study cabinet government dissolution with a unified model that allows them to account for both the particular attributes of the cabinet as well as the stochastic event process. Although there was disagreement in the literature about the proper specification of the hazard rate, this model was later applied to the duration of governmental leaders. Alt and King (1994) found that the risk of experiencing the event, in this case the removal of the leader from power, increased over time just as it did for cabinets. While these studies included characteristics of the political system, economic factors were omitted. The addition of economic indicators such as the inflation and unemployment rates improved the predictive power of the models and showed that poor economic health contributes to the collapse of governments (Warwick, 1992).

The duration of armed conflict or peace is common event history topics in international relations. Many conflict scholars are interested in the role third-party intervention plays in the duration of civil and interstate wars. The effect of the international community on duration is conditional on both the actor and the actor's relationship with the warring parties. For instance, Aydin and Regan (2012) found that engagement by third-party state increases the duration of civil wars if the states support opposite sides of the conflict. Duration is decreased, however, if the states unilaterally support the same side. Similarly, the outcome of a conflict, e.g., negotiated settlement, military victory, and the presence of international peacekeeping forces, have also been shown to affect the likelihood of a conflict reignigting (Mason et al., 2011).

In the U.S. context, duration models have been used to study policies, institutions, and behavior. The widely used Berry and Berry model of policy diffusion was developed in the event history context (Berry and Berry, 1990, 1992, 1994). The model allows for both internal and regional characteristics to influence the adoption of new policies and has since been applied a variety of policy areas, such as the adoption of climate protection and antismoking legislation (Krause, 2010; Pacheco, 2012, respectively). Committee tenure (Katz and Sala, 1996) and tenure in office more generally (Jones, 1994) are influenced by electoral systems and the calendar. The political environment also affects the duration of presidential appointee confirmation, with the hazard function decreasing as ideological distance between the president and Congress increases (Shipan and Shannon, 2003; Segal et al., 2010). An event history framework has also been applied to the timing of voting decisions. Box-Steffensmeier and Sokhey (2010) show that political engagement, ideology, and strength of partisanship all increase the hazard rate thereby reducing the time it takes for a voter to go from 'undecided' to 'decided.'

Time Series and Cross-Sectional Analyses

In many instances, data can be collected where cases are spread both within and across time points. Cross-section data have multiple units observed at a given time point but PCSTS involves multiple cross-sections observed at different points in time. Since OLS assumes errors are independently and identically distributed, the PCSTS framework requires its own set of methods. PCSTS methods attempt to address the complex multilevel structure of multiple units observed over time. A unit x_{it} is correlated with x_{jt} by virtue of being observed at the same point. Depending on the type of cross-sectional data, x_{it} may also be correlated with x_{it-1} if the same unit is observed at multiple time points. There are several types of PCSTS data, and each structure poses different challenges to data analysts.

For starters, a true panel design involves an identical set of cases repeated over multiple time points. Panels are frequently comprised of survey respondents who are interviewed a small number of times such as a special subset of election study respondents. Panel election studies began with the Columbia school (e.g., Lazarsfeld, 1948), although repeated interviews during the course of a single campaign limited the representativeness of the sample. In addition to problems with generalizability, election panels can also suffer from attrition. A variety of factors, from frequency of contact, method of contact, and even mortality can all affect the recontact rates.

Alternatively, the same set of countries observed over the same set of years also represents a type of panel design. As with most time series methods, models for analyzing panel data were developed to handle econometric data with a large enough N to capitalize on the estimator's asymptotic properties. Methods such as dynamic panel analysis, Markov-switching models, differencing, and lagged dependent variables are available.

Deviations from a true panel fall into a range of types we can classify as pseudo-panels in which there are multiple cross-sections of data but not all cases are found in each wave. One variety of pseudo-panel structures is the unbalanced panel where some cases are observed more than once, but each observation does not appear in every time point, e.g., Carson et al. (2010) study Members of Congress running for reelection from 1956 to 2004. The range of methods available to account for time dependencies quickly dwindles here. Since some cases appear in the data but once, differencing data of using lagged variables will drop out those case and potentially cause problems of selection bias. Fixed effects by time point or panel-corrected standard errors are common, but imperfect, solutions (Beck and Katz, 1995).

Two last types of pseudo-panels are the rolling and repeated cross-sectional (RCS) designs. In both of these cases each observation appears a single time in a data set that consists of multiple waves. In a rolling design, typically an election study, the survey designers choose their set of respondents at the beginning and then roll out the survey to subsets of respondents at prespecified dates. The American National Election Studies conducted the first rolling cross-section in 1984 and it was later adopted by the Annenberg Election Study and the British Election Study.

Repeated cross-sectional designs include the wider set of designs in which observations are collected *post hoc* and assembled into a larger data set (Lebo and Weber, 2014). An RCS data set may include hundreds of months of individual-level data from consecutive public opinion surveys, or it could be Supreme Court cases nested with terms of the Court, or some other case for which the time the data are collected requires attention in the modeling framework. Lebo and Weber (2014) demonstrate how RCS data can be studied at two levels of analysis – aggregate and individual level – in a multilevel model that includes time-varying parameters. In any study where cases are nested within distinct time periods, researchers should pay close attention to the error structure to be sure model estimates are trustworthy.

Conclusion

Overall, the wide variety of data structures requires researchers to think carefully about how time plays a role in the phenomenon they study. Time can either be treated as a nuisance or as a substantively interesting variable across a variety of political science subfields and a wide array of research questions. Those treating time as substantively interesting have continued to advance time series analysis since its introduction to the field in the early 1970s. This is in part due to the increased availability of a range of data spanning sufficiently long time periods. In addition to more readily available data, traditional data sources are being measured with increasing frequency. For example, presidential approval was once only available quarterly yet is now available daily from Gallup. Similarly, the Annenberg Election Survey (The survey will resume in 2016.) tracks opinion about campaigns, candidates, and issues on a daily basis.

To date, most methods used to analyze temporal effects have been imported by political scientists from other social science disciplines. Although these methods are theoretically applicable to political phenomena, they may require tweaking to adapt them to political science data structures. Researchers should pay special attention to the properties of their data before wholesale adoption of imported techniques. Monte Carlo studies are an underutilized way to determine how an estimator responds to changes in level of integration, seasonality, and series length – all of which vary between data sources. Having a better grasp on how the methods respond to political science data allows a more informed decision about the appropriate estimator.

It should come as no surprise that unpacking the relationship between various political phenomena over time is challenging as many factors are closely intertwined. Time series analysis provides a unique opportunity to approach questions of causality using observational data. While Granger causality tests can identify if changes in one variable of interest temporally precede changes in another, it is a common misperception that these tests alone are enough to rule out endogeneity (Charemza and Deadman, 1997). Indeed, a battery of tests exist to determine if a one variable is weakly or strongly exogenous to another. If one series is weakly exogenous, there is no reciprocal causality and modeling is simpler. However, if there is unmodeled reciprocal causality, estimates become biased and inefficient. Thus researchers should explore exogeneity tests and utilize multiple equation (near-)VARs to disentangle reciprocally causal relationships where they exist.

Overall there is much to be learned from incorporating time into studies of politics. The many statistical problems inherent in data that evolve over time can wreak havoc on our understanding of political relationships. But, even setting those aside, modeling temporal effects provides interesting insights that cannot be gained from the single snapshot in time that cross-sectional analyses provide.

Abstract

Karl Popper established falsificationism as a basic orientation in modern philosophy of science. Falsificationism, as opposed to verificationism, claims that the main research activity is to invalidate a theory by observation or experiment; confirmation or corroboration of a theory relies on the failure of attempted falsifications. Following Hume, Popper denied the validity of induction from limited observations to universal regularities. For Popper, the dynamics of theories consists of replacing falsified hypotheses with better ones, with the aim of approaching objective truth. Popper was an objectivist and realist, strongly opposed to subjectivistic approaches; he considered probability as a strictly objective measure rather than a degree of (rational) belief. Popper later adopted a form of evolutionary epistemology, which considers all life to be problem solving by trial and error. Most fundamentally, he extended falsificationism to the methodology of critical rationalism, encompassing all areas of reasoning, including metaphysics. Popper defended indeterminism as the basis of free human action. He proposed a triad of causally interacting worlds of body, mind, and contents of thought. In his social and political philosophy, he was opposed to historicism as a deterministic view of history, and proclaimed the idea of an open society as a social framework for responsible action.

Popper's Life

Karl Raimund Popper was born in Vienna, Austria, on 28 July 1902. His father, Simon (Siegmund Carl) Popper (1856–1932), who had come from Bohemia to Vienna, was a well-established lawyer with his offices and family residence in the center of Vienna. Karl Popper's mother, Jenny Popper (neé Schiff) (1864–1938), came from a musical family and was a gifted pianist herself. Both Simon and Jenny Popper were Jews by origin, but converted later in their lives to Protestantism. Besides their son Karl, they had two older daughters, Dora (1893–1932) and Anna Lydia (1898–1975).

Karl Popper left high school (Franz Josef Gymnasium) at the age of 16 without a degree, moved out of his parents' home and attended lectures at the University of Vienna on various subjects, in particular mathematics, philosophy, physics, and psychology. Besides occasional jobs to earn his living (e.g., coaching American students), Popper was engaged in social activities. For some time, he worked as an assistant of Alfred Adler on neglected children. Hints in Popper's autobiography indicate that this connection (through which he got acquainted with Adler's 'individual psychology') contributed to Popper's later critique of psychoanalysis as a 'pseudoscience.' In his youth, Popper had a strong favor for democratic socialism. For a few months, he even considered himself a communist, from which he refrained, in 1919, after witnessing a shooting incident in which socialist workers were killed by police forces. This experience of a useless sacrifice of lives demonstrated to him the futility of ideologies. A second, more intellectual experience in 1919 was his taking interest in Eddington's test of Einstein's eclipse predictions carried out at an expedition of the Royal Astronomical Society, whose results gained widespread publicity at the time. During a total solar eclipse, which was observed from West Africa and Brazil, a shift of apparent position of stars in the presence of the sun's gravitational field could be established, as predicted by the general theory of relativity. This coined Popper's later insistence that scientific theories develop by exposing them to possibly falsifying experience. Around that time, Popper visited a lecture by Einstein in Vienna.

The young Popper also tried manual work. From 1922 to 1924, he was an apprentice to a cabinet maker. At the same time, he passed the high school exams ('Matura') as an external participant and formally enrolled as a student at the University of Vienna. He also considered becoming a musician. After being disappointed with the sort of music cultivated in the Schönberg circle, he enrolled as a student of Church Music at the Vienna Academy of Music ('Konservatorium') and stayed there for 1 year. He was admitted upon submission of a fugue for organ in F sharp minor. Besides his scientific studies at the University of Vienna, in 1924 he qualified as a primary school teacher. Since no appropriate teacher's post was available at the time, Popper worked as a social worker with neglected children.

In 1925, Popper became a student at the Pedagogic Institute of the City of Vienna, where he stayed until 1927. This institute, in which Popper was admitted to due to his status of a social worker, had been newly founded. It was linked to the University, though formally independent. In today's terms, its purpose was to scientifically accompany and evaluate the school reform movement. This school reform movement had been politically supported by the Austrian social democrats since 1919 and was in 1925 still very strong in Vienna. It was characterized by ideas of abolishing school learning as an accumulation of facts in favor of developing a more autonomous and participating attitude. The influence of these ideas on Popper should not be underestimated. His later criticism of what he calls the 'bucket theory of knowledge,' i.e., the inductive generation of knowledge by collecting facts, is related to pedagogic proposals on how learning proceeds or should proceed. Actually, Popper's first published papers were in this field and appeared in journals belonging to the school reform movement. The very first one *Über die Stellung des Lehrers zu Schule und Schüler* (*On the teacher's attitude toward school and students*, 1925) is very significant in this respect.

At the pedagogic institute, Popper met Josefine Henninger (1906–85), who was training as a teacher and who was to become his wife in 1930. (They had no children.) He also met the psychologist Karl Bühler and the philosopher Heinrich Gomperz, both of them professors at the University. They were of crucial importance to Popper's intellectual development. It was through discussions with Gomperz and reading his works that Popper shifted away from any psychologistic approach to the philosophy of science. From Bühler, he adopted the distinction of expressive, signaling, and descriptive functions of language, which still figured prominently in Popper's late metaphysical writings.

In 1928, Popper completed his PhD in Psychology with Karl Bühler and Moritz Schlick as examiners. The subject of the thesis was *Zur Methodenlehre der Denkpsychologie* (*On the Methodology of the Psychology of Thinking*, 1928), a work that combined Popper's interest in psychology with the methodological bias, which he had finally shifted to during his time at the Pedagogic Institute. In 1929, Popper qualified as a teacher for secondary schools ('Hauptschulen'), and in 1930, he became a teacher in Vienna.

Since 1922, Popper had been in contact with members of the Vienna circle, a group of philosophers around Moritz Schlick who propagated what they called 'logical positivism,' a version of empiricism, which made strong use of modern mathematical logic as a tool of philosophical analysis. Mathematical logic had already been developed by Gottlob Frege (1848–1925) and Bertrand Russell (1872–1970) decades ago, but had not been appropriately appreciated within the established academic philosophy. Though never a member of the circle, Popper attended its sessions occasionally and was in contact with several of its members, in particular Rudolf Carnap, Victor Kraft, and Herbert Feigl. Although he shared certain basic attitudes of the Vienna circle, in particular the plea for a scientifically oriented philosophy, he was highly critical of other tenets, such as the theory of meaning and the form of empiricism propagated. Motivated by Feigl, he put this criticism into a large manuscript in two volumes *Die beiden Grundprobleme der Erkenntnistheorie* (*The Two Basic Problems of Epistemology*, published in 1979, the second volume only as a fragment). A shorter version of the second volume of this manuscript was published in 1934 as *Logik der Forschung* (*Logic of Scientific Discovery*), which was to become his main work.

The book was well received. Reviews appeared in many journals. Even Einstein wrote Popper a letter after the book was sent to him through intermediates. In 1935 and 1936, Popper received invitations to England, where he lectured at Bedford College and Imperial College, London, at the London School of Economics and at Cambridge. He made a lot of contacts. Of most importance for his later career were those with Ernst Gombrich and Fritz Hayek. However, attempts to find a position in England did not materialize, and in 1937 he emigrated with his wife to New Zealand, accepting an offer of a lectureship at Canterbury University College.

During the time in exile, Popper intensified his interest in social and political philosophy and in the philosophy of history, besides continuing his research in logic and philosophy of science. From that time on, he published mainly in English. He wrote a series of articles *The Poverty of Historicism* (Popper, 1957a originally 1944–45); and, more importantly, his two-volume classic *The Open Society and Its Enemies* (Popper, 1945). For both works, he had to struggle to find a publisher. Due to the *Open Society*, he acquired his initial postwar reputation and, in particular, his post, from which he carried out all subsequent work. Through the intervention of Hayek who, together with Gombrich, had made the publication of the *Open Society* with the publisher Routledge possible, he was offered a readership in Logic and Scientific Method at the London School of Economics in 1945, which Popper took up early in 1946, shortly after publication of the *Open Society*. In 1949, he received a professorship of the same title at the London School of Economics, which he held until his retirement in 1969.

During the first 5 years of his stay in Britain, he was sort of a 'star.' The *Open Society* made him a quite popular theoretician of political liberalism. It has often been said that this book filled some intellectual vacuum in the postwar period. Popper was invited to many places and, at the same time, had a substantial audience at the London School of Economics. In the 1950s, he shifted more to working from home with less institutional involvement. At the same time, his research interests moved away from political and social philosophy and back toward the subject of the *Logik der Forschung*, i.e., the methodology of the natural sciences. However, the first English edition of this book appeared only in 1959, with a lot of material added compared with the German original. Many other books and plenty of papers followed. Up to his death, Popper produced an enormous scientific output and had a vast correspondence. From the mid-1960s on, Popper received a great number of prizes and honorary degrees in many countries, including Knighthood and Membership of the Royal Society in Britain. He died on 17 September 1994 in London. His ashes were buried in Vienna, where his wife had died in 1985.

Popper's Work

Popper's work covers nearly all areas of theoretical philosophy. His overall profile is that of a great philosophical classic. However, most important are his contributions to the methodology of science, where he established falsificationism as one of the basic orientations in the modern philosophy of science.

The basic claims of falsificationism are put forward in the *Logik der Forschung* (1934, official year given in the book: 1935). Most of Popper's later methodological contributions can be viewed as elaborations or amendments of what was already stated in his first book. Even Popper himself treated the *Logik der Forschung* like a classical text, with all changes in the first English translation (*The Logic of Scientific Discovery* 1959) as well as in the later 10 German and 10 English editions, as a system of footnotes and appendices to the 1934 edition.

Falsificationism can be described as a 'why not' methodology in contradistinction to a 'why' methodology with respect to scientific theories. According to Popper, a scientific theory is posed without any prior justification. It gains its confirmation, or 'corroboration,' which is Popper's preferred term in later writings, not by experimental evidence demonstrating *why* it should hold, but by the fact that all attempts at showing *why* it does *not* hold have failed. The main activity of an experimental

researcher is trying to refute or '*falsify*' a scientific theory, rather than to justify or '*verify*' it. Theoreticians who design theories should do this in such a way that they can be refuted most easily. In no case must a theory be immunized against possible falsification, e.g., by the introduction of ad hoc hypotheses. We rely on a theory only because we have not managed to falsify it (so far), not because we have any positive or direct reasons in its favor.

His own theorizing, and especially the idea of falsificationism, is considered by Popper as proposing 'methodological rules.' These methodological rules have to prove fruitful in the understanding of scientific research and, particularly, of scientific progress. The main argument in favor of his falsificationist proposal is that the converse proposal, which is called 'verificationist,' is bound to fail. Verificationism, which underlies the 'inductivist' methodology, claims that a scientific theory is supported by a collection of verifying instances. However, as has already been established by David Hume (1711–76), the inductive reasoning from a finite set of observations to a general statement is not logically valid if the domain of reasoning is infinite or at least indefinite. Furthermore, any attempt at creating a special nondeductive form of reasoning (an 'inductive logic') can only be justified by means of induction itself, thus ending up in a vicious circle. To quote Popper's famous example, no observation of white swans can verify the general statement that all swans are white.

Popper's falsificationist methodology rests on the assumption that unlike verification, falsification of a general statement by experimental or observational means is without any logical problem. The statement 'all swans are white' can be falsified by the observation of a single black swan. The logic involved here is just ordinary deductive logic, due to which the falsity of an instance derived from a general hypothesis falsifies the hypothesis itself. Seemingly singular statements such as 'The planet Pluto has a moon,' which at first glance seem to be verifiable but not falsifiable, are viewed by Popper not in isolation, but as embedded in a general theory and therefore are no counterexample to what he calls the 'asymmetry between verification and falsification.'

More complicated is the example of statistical theories, where definite falsification is not possible. Here, Popper applied as an additional methodological rule that what is extremely unlikely can be neglected as something, which cannot be reproduced deliberately. This allows Popper to cope with the standard way of rejecting statistical theories by means of a critical test (usually defined by stipulating a level of significance).

In traditional methodology, particularly that of the Vienna circle, inductivism was tied to empiricism and guaranteed the connection between theoretical statements and their empirical basis. In falsificationism, the empirical significance of theoretical statements is kept by relating them to basic statements, which possibly falsify them. However, these basic statements are no longer purely observational in some epistemological sense, but are themselves theory-laden from the very beginning. Even elementary perceptual evidence has to rely on theoretical assumptions. Thus, Popper rejects any semantic division between theoretical and observational statements and, especially, the claim that a particular sort of certainty comes with the latter. According to Popper, the validity of basic statements can only be fixed in the course of the testing of a theory, and, in the end, this fixing is a matter of convention. This variant of conventionalism, which enters Popper's approach in addition to the conventionalism inherent in the choice of methodological rules, has repeatedly been the subject of criticism.

For Popper, the distinction between a theory that can be falsified by means of basic statements and one that is not falsifiable serves as a demarcation criterion for empirical science versus metaphysics. However, metaphysics, though not falsifiable, is not meaningless. Metaphysical statements may serve useful purposes, even within science. For example, the principle of causality ('any event can be causally explained'), which cannot be falsified and is therefore metaphysical, can be viewed as the useful methodological rule never to abandon the search for laws that explain observed facts. This view of metaphysics is less rigid than that of the Vienna circle, who considered metaphysics to be meaningless throughout. It allows Popper to sharply criticize certain nonfalsifiable theories as 'pseudosciences' (such as psychoanalysis), but nevertheless to make sense of certain traditional philosophical claims or to appreciate the fruitful role of metaphysical research programs in the history of physics ('A metaphysical epilogue,' in *Quantum Theory and the Schism in Physics* 1956, published 1982b).

In his later works, Popper extended the methodological approaches of the *Logik der Forschung* toward a general account of the dynamics of scientific theories ('Truth, rationality, and the growth of scientific knowledge,' in *Conjectures and Refutations* 1963). According to this view, theoretical progress is made by successive critique and revision of existing theories, which is governed by the idea of objective truth. Scientific progress works by replacing a falsified theory with a new one, which, in the ideal case, is more encompassing than the previous one in that, while coping with the new results, it also covers the unfalsified instances of the old theory. This appeared to be the case with classical and relativistic gravitational theories in the presence of the results of the 1919 solar eclipse observations, which were so impressive to the young Popper. His later claim is that the new and more encompassing theory is nearer to the truth than the older and more special one, even if it should, at some point, become falsified itself. Popper has tried to characterize the distance of a theory from truth, its 'truthlikeness' or 'verisimilitude,' in numeric terms. Considerable work has been carried out in recent decades to develop improved measures.

Within the revision of scientific theories, Popper strongly distinguishes between hypotheses being tested and background knowledge, which, though testable in principle, is not being questioned at the same time. This distinction makes the falsification of parts of a theory possible, and not only the falsification of a theory as a whole. Therefore, Popper pleads to formulate theories in a modular way such that its parts can be tested independently of each other. He is opposed to 'holistic' views of theories, according to which, in a single test, the whole theory (Pierre Duhem) or, even more radically, all our theoretical knowledge including logic and mathematics (W.V.O. Quine) is at stake. Popper defended his model of scientific progress as a change of scientific hypotheses by means of falsification against historic approaches, which denied the rational character of scientific change. So he was strongly opposed to Thomas S. Kuhn's account of scientific revolutions

as irrational changes without the concept of 'progress' being applicable. Similarly, he argued with Imre Lakatos (1922–74) and Paul K. Feyerabend (1924–94), who started as Popperians, but later on made changes in falsificationist methodology by weakening and relativizing Popper's strict idea of progress by critical testing.

In *Evolution and the Tree of Knowledge* (1961, published 1972 in *Objective Knowledge*), Popper embedded the idea of theory change by falsification and revision within a general theory of the evolution of knowledge. Here 'knowledge' is viewed as a form of adaptation of an organism to the environment. Popper's schema of progress from problems via falsification to new problems is interpreted as the evolutionary transition from organisms via natural selection to those that are better adapted. By viewing all life as problem solving (*All Life is Problem Solving* 1994c), Popper claimed to combine theories of biological evolution with theories of scientific progress, relating his approach to evolutionary epistemology in the sense of D. Campbell. However, it must be emphasized that, unlike most evolutionary epistemologists, Popper was not a naturalist. He insisted that the cultural scientific evolution is rational and based on conscious and deliberate criticism, not on natural selection governed by chance.

In his later work, Popper also replaced the narrow concept of 'falsification' with a broader concept of 'criticism' or 'critical examination.' This broader concept not only applies to scientific theories that are formulated in a logical language, but also to philosophical claims that are metaphysical. It involves tests of consistency and the investigation of how far the theory in question is able to solve particular problems. This orientation, with critical examination as its cornerstone, was called 'critical rationalism' by Popper and has since become the standard denomination of the Popper school. The main examples of Popper's dealings with metaphysical problems are his treatment of determinism and his philosophy of mind. Quite independent of problems of quantum mechanics, which often serve as arguments against determinism, in *The Open Universe: An Argument for Indeterminism* (1956, published 1982a), he developed an indeterministic world view. In 'Of clouds and clocks' (1966, reprinted in *Objective Knowledge* 1972), he extended this view with arguments for the openness of the future for free action. In the mind–body debate, Popper defended a mind–body dualism ('Language and the Body–Mind Problem,' 1953, reprinted in *Conjectures and Refutations* 1963), which he later extended to a model of three worlds of (1) physical entities, (2) mental states, and (3) objective contents of thought, which causally interact. This approach gained much attention through his discussions with J.R. Eccles which, together with their separate contributions, are presented in their joint book *The Self and Its Brain* (1977).

Epistemologically, Popper was an outspoken objectivist and realist. On the Popperian view, our theories are not just methodological instruments or means of acquiring (some degree of) certainty about something, but attempts at explaining the real world. As reality is described by means of true sentences, this is another way of claiming that the goal of science is truth. Part of Popper's objectivism and realism is his rejection of any subjective interpretation of probability. In particular, he was strongly opposed to Bayesianism and its view that scientific progress is just changing the probabilistic degree of belief in certain propositions, which means that scientific dynamics is probability dynamics (*Probability Magic or Knowledge Out of Ignorance* 1957b). Both the probability of hypotheses, for which Popper coined the term 'logical probability,' and statistical probability, which may be part of a hypothesis, are objective probabilities reflecting properties of what they are attributed to. Logical probabilities are inversely proportional to the content of a theory, the less probable theory having a higher content. Statistical probabilities, which in the *Logik der Forschung*, were interpreted as relative frequencies, were later viewed as objective 'propensities' of experimental designs to develop certain outcomes (*Realism and the Aim of Science*, 1956, published 1983). This propensity interpretation of probability claims to be a solution of the problem of assigning probabilities to singular events, rather than only to events as members of a given sequence or set of related events.

Popper's attitude against probabilities as degrees of belief does not contradict the fact that he attempted to measure the degree of corroboration of a theory in probabilistic terms. However, first of all, Popper's degree of corroboration, though relying on probabilities, is not a probability itself, i.e., it does not obey the laws of the calculus of probability. Second, the degree of corroboration is intended as a strictly objective measure, which reflects the way the hypothesis in question was subjected to falsification, and is definitely not meant as a degree of rational belief in a hypothesis. According to Popper, epistemology is the methodological treatment of objective scientific contents and not a theory of the knowing subject ('Epistemology without a knowing subject,' 1967, reprinted in *Objective Knowledge* 1972).

Popper's social and political philosophy, which was developed during his emigration in New Zealand and published in *The Poverty of Historicism* (1944–45) and *The Open Society and Its Enemies* (1945) can, to some extent, be viewed as an application of falsificationism to the area of social interaction. By 'historicism,' Popper denoted the claim that the methodology in the historical and social sciences differs fundamentally from those in the natural sciences but, nevertheless, allows one to formulate objective laws of historical development, which cannot be changed by subjective action. The standard example is the Marxist philosophy of history (historical materialism). In contradistinction to that, Popper put forward the idea of 'piecemeal social engineering,' i.e., of a development of social institutions in small steps, which can be revised and whose potential damage can be controlled. According to Popper, piecemeal social engineering can be combined with a falsificationist form of social research, which is based on trial and error as it generates models for social development. For areas of historical and sociological research that are interested in the explanation of single events rather than the testing of general laws, Popper proposed the procedure of a 'logic of the situation,' which describes the acting of individuals under the hypothesis of rational purpose-oriented behavior within a certain social situation. In this context, he defends the autonomy of sociology against psychologism, as this situation is described in objective terms by reference to social institutions, etc. Since 1961, Popper defended this account of social theorizing against representatives of the neo-Marxist Frankfurt school in Germany, in particular, Theodor W. Adorno and Jürgen Habermas, in a dispute, which became known as the

'positivist dispute in German sociology,' and which made Popper well known to a wider audience in the German-speaking countries.

The *Open Society* extends the critique of historicism to a critique of the philosophical theories of state and society by Plato, Hegel, and Marx, which Popper considers to be philosophical precursors of political totalitarianism. According to Popper, they advocate the idea of a closed society, which is a collectivistic and organismic whole, without the distinction between natural and cultural laws. In an open society, which Popper strongly favors, individuals are personally responsible for their decisions and can therefore be critical to social regulations. Popper argues that the traditional question 'who should rule' ought to be replaced by the question of how to minimize the risk of bad rulers and how to get rid of them once they are in power. For Popper, the long-standing philosophical discussion about the best rulers belongs to justificationist thinking that has to be abandoned in favor of critical thinking, just as in general methodology. The utilitarian principle of maximization of happiness should give way to the idea of minimizing suffering.

Although there appears to be a lot of moralizing both in the *Open Society* and in many short papers and interviews on questions of morals and politics given toward the end of his life, this should not be understood as fragments of an ethical theory. For Popper, there is no such thing as ethics, because ethical sentences are not propositions in the logical sense that one could argue for or that one could reject. However, there are moral actions. These are actions that are carried out by someone who is aware of their consequences. Since the consequences of actions can be critically examined in the sense of critical rationalism, moral decisions are not irrational.

Relevance and Impact of Popper's Philosophy

Popper's methodological program was revolutionary as it reverted the established conceptual order between certain fundamental notions. He put 'negative' concepts such as 'falsification' and 'rejection' first, and made 'positive' concepts such as 'acceptance' or 'corroboration' dependent on them. While, according to the traditional philosophical view of science established ever since Bacon, acceptance of a theory is based on the direct generalization from observation, according to Popper, it can only rely on failed rejection. It is therefore correct to speak of Popper's 'negative methodology.' As Popper tried to show in his later writings, this is not just a program for the natural sciences, but applies to any area of scientific reasoning and even to metaphysics, where negative concepts such as that of 'criticism' come first. The credit we give to a conjecture is based on the fact that refuting it by criticism has been unsuccessful. This program is even the basis of Popper's political philosophy. The negative question of how to restrain political power and to remove bad rulers from power is of primary concern compared with the positive one of whom to give power. Popper's negative methodology is a unified view of rationality under the header 'critical rationalism.'

This comprehensive perspective of theoretical reasoning and social and political action makes Popper's philosophy comparable with that of great classics like Aristotle or Kant. It was also one of the sources of the great success, which Popper enjoyed still during his lifetime. As a general and unifying view, 'critical rationalism' is, of course, liable to oversimplification and, among certain adherents of Popper there has, in fact, been a considerable amount of that. On the other hand, it was only critical rationalism as a general orientation that could publicly compete with the eloquence of hermeneutic or neo-Marxist approaches. Philosophical theories like logical empirism, though with respect to intellectual clarity and responsibility by no means behind Popper's, would have been too academic to develop any major public significance.

In fact, it is not very difficult to give an outline of the basic principles of critical rationalism to somebody who is not a trained philosopher. Critical rationalism is an approach that offers something at any depth of understanding. Popper's works both cover extremely intricate discussions, e.g., of the methodological role of probability, whose significance can only be judged by highly specialist researchers, and general questions of reasoning, society, and politics at a level accessible to anybody who is really interested. With the exception of the chapters on probability and on quantum mechanics and of the appendices, the *Logik der Forschung* can easily be studied without deep expertise in academic philosophy. Even from a first reading, the average student would gain a preliminary understanding of falsificationism. Matters of presentation are very important in philosophy, and Popper was a master in that. His language is extremely clear and nonpretentious, which distinguishes him from many other philosophers, particularly in the German tradition.

Popper made a strong impression on politicians of various directions, although he was himself never involved in party politics. Both conservative and social democratic or labor politicians have referred to Popper to justify their respective programs and proposals. The term 'open society,' which Popper coined, has become widely accepted as a designation of basic features of a democratic state.

Popper's lasting impact on the shape of philosophy of science was not only due to his methodology in the narrower sense, but also due to his drawing attention to the *dynamics* of science. It is significantly due to Popper's influence that the philosophical and logical reconstruction of scientific reasoning is not just a modeling of static theories in logical terms but, to a great extent, an account of theory dynamics, i.e., of what it logically means that a theory is being given up or revised. The combination of philosophy of science with the history of science, which is reflected in many divisions of university departments, denominations of chairs, etc., emerged on this background, as philosophical theories of theory dynamics have to be tested against the historical development of theories, and, conversely, the proper understanding of historical developments requires appropriate methodological tools. Although today's theorizing differs in many respects from what Popper argued for and often contradicts his claims (i.e., Bayesian approaches in the field of belief revision), the research program of putting dynamics of theories first in the methodology of science is unthinkable without Popper's revival of the induction problem and his negative methodology as a proposed solution.

The influence of Popperian theories on the 'working scientist' should not be underestimated. If scientists have any interest in the methodology of science at all, they would know of Popper's approach. This is particularly true of the social and

behavioral sciences. There, falsificationism figures prominently in textbook chapters dealing with methodological questions. One may speculate why falsificationism is so appealing to social scientists. A possible answer might be that statistical methodology, which lies at the heart of the social sciences, has a bias toward falsification. According to the most widespread statistical methodology, which is a combination of accounts by R.A. Fisher and by J. Neyman and E. Pearson, the rejection or falsification of a statistical null hypothesis at a certain level of significance is a direct and uncontroversial result, whereas the acceptance of a positively formulated statistical hypothesis is only indirect and preliminary (as it depends on features such as sample size) and, in any case, is technically more involved.

Certain results of modern computer science have challenged Popper's view on induction. His methodology comes along with the claim that we always start with theories or hypotheses which, in the course of time, are then revised to better hypotheses by trial and error. How a new hypothesis is formed was not the subject of rational investigation for Popper. In artificial intelligence and, in particular, in learning theory, algorithms have been developed to generate theories that fit given data. This does not contradict falsificationism, as these heuristically developed hypotheses would then have to be tested, just as falsificationism claims. However, the availability of such procedures destroys the myth that a theory is the extrarational product of a genius or some sort of accidental mutation, and lays the foundation for algorithmic inductive heuristics as a rational enterprise.

There are a lot of questions in the technical development of the Popperian approach, e.g., his treatment of probability and of logic, whose significance for future developments has still to be proven. Something similar holds for Popper's metaphysical theories. However, these are less important details compared with his basic methodological claims, which will remain a standing challenge.

Popular Culture

Abstract

In this article I present some conceptual frameworks for examining popular culture. I discuss how popular culture includes media, sports events, advertisements, street fairs, and tourism. I then describe how popular culture provides us with a lens to trace larger historical processes and public debates on issues as wide-ranging as family and kinship, nation, intimacy and sexuality, and the transnational. I posit that, in the contemporary world, it is essential to examine popular culture in its transnational dimensions. Popular culture is also a critical node in the generation and circulation of not just ideologies but also regimes of affect. In every sense, popular culture is socially and politically consequential. I trace different scholarly perspectives on popular culture, such as feminist critique, critical theory, cultural studies, and historical frameworks. I conclude by considering how digital media have altered how we think of popular culture, such that our previously held assumptions about sociality and politics, distance and proximity, and virtuality and reality are now altered.

For most of us, popular culture is a source of entertainment. It encapsulates media (such as film, television, print media, and digital ('new') media), and includes sports events, advertisements, street fairs, and tourism. We engage with popular culture because we get pleasure from it; at the same time, we are also informed by it. We usually associate information with news rather than with entertainment. But other forms of popular culture that we often associate with for 'mere entertainment' – for instance, tourist practices, popular music, films, sports, and television programs – also inform us in profound ways. For example, a romance novel might instill in us expectations about intimacy, gender and sexuality. Popular culture plays an important role in shaping our personal and collective identities. It also provides us with an analytic lens to understand sociohistorical processes such as class, gender and sexuality, nationalism, and transnationalism.

Changes in popular cultural texts often articulate in wider social and cultural changes. Consider the contrast between the harmonious, heteronormative nuclear family portrayed in the *Cosby Show* in the 1980s, and the family we see in the U.S. sitcom *The Modern Family* which depicts the lives of members of three interrelated families. *The Modern Family* is multiracial and includes a gay couple and an adopted Vietnamese child. The past few years have also witnessed an efflorescence of digital media that have been immensely powerful in altering the cultural landscape of many societies: a range of relationships are now forged on Facebook, flash mobs converge through Twitter, and the internet has become a vital source of connectivity in many parts of the world. In recent years, digital media have also played an important role in politics, whether through online political fund raising or by galvanizing rebellion in societies where other media may be censored.

What Is Popular Culture?

In the modern world, popular culture is available to what we may call 'the public' or 'masses' of people. For this to happen, there have to be established means of production, distribution, and reception. For example, for a soap opera to exist there have to be a crew of script writers, actors, a director, a producer – in other words, a crew of people who work behind the scenes and in front of the camera. There also has to be a means to finance this production: in capitalist societies, soap operas are financed by sponsors who pay for the production and telecast of a soap opera in exchange for being able to advertise on it. This is how the term 'soap opera' originated: soap operas were sponsored originally by manufacturers of detergents. Even today, the manufacturers of detergents and other household goods like washing machines, kitchen appliances, and cleaning agents are key advertisers on soap operas. There also needs to be an infrastructure for its distribution. This is where television networks come in. Very often, television networks are part of larger media conglomerates or groups of companies. Television production is, therefore, part of a larger system of industrial production.

Popular culture presents us with a vantage point on the world: it is a domain that shapes our sense of self or our identity. Not only is it generally available to a large number of people, it also responds to and creates points of identification among large groups within a community or nation. Popular culture plays an important role in constituting and representing the public to itself. It is public in two senses: not only does it circulate widely and is often associated with public exhibition and display, it also configures 'the public,' 'the nation,' 'society,' 'culture,' 'family,' and other collectivities. In the contemporary world, transnational media play a primary role in the circulation of popular cultural texts. From a sociological viewpoint, popular culture is probably the most important influence on the lives of millions. However, it is important to recognize that viewers are not just unthinking targets of popular culture. Rather, in order to understand the cultural significance of popular culture, we need to examine how its consumers respond to, reinterpret, and employ its messages.

Popular culture is a site of struggle between dominant discourses and forces of resistance. It contains 'points of resistance' as well as ' moments of supersession'; it forms a 'battlefield where no once-for-all victories are obtained but where there are always strategic positions to be won and lost'

(Hall, 1981, p. 233). Mass media may open up a 'zone of debate' about issues current in a given community (Gupta, 1995). For instance, in the 1990s, television shows like the U.S. sitcom *Ellen* enabled the rearticulation of debates around homosexuality. Popular culture, then, does not simply 'reflect' the lives and worlds of audiences; nor does it 'impact' these worlds or lives in a simple way. Instead, popular cultural texts are social formations in and of themselves.

In addition, we need to attend to three other dimensions of popular culture in the contemporary world. One, we need to examine popular culture in terms of its transnational dimensions. Transnational media have played a critical role in connecting viewers/readers/consumers in different parts of the world. Satellite television allows us to keep up with the news, weather updates, and entertainment programs in different parts of the world: thus, for instance, viewers living in London are able to watch television soap operas at the same time as their relatives in the United States. The internet has changed previous conceptions of 'breaking news' by enabling us to engage with events even as they unfold in different parts of the world.

Second, the proliferation of media has altered how we engage the world of information and entertainment: we do not just listen to music, we watch music videos; we stream movies on our computers; we listen to ringtones on our cellphones; and so on. As a result, rather than focussing on a single medium, scholars of media prefer to trace the different media that form a media-saturated *landscape* or media *ecology*.

Finally, we need to conceive of popular culture as a node for the generation and circulation of not just ideologies but, equally importantly, of affects. Media scholars now recognize that in addition to being ideologically interpellated by media, media also work on us through the affective regimes they generate and circulate. These regimes of affect blur the line between feeling and thought, the corporeal and the cognitive, and the individual and the collective: the regimes of affect circulated through media are transitive, yet have a profound effect on how we position ourselves in the world. For instance, media played a critical role in the generation and circulation of the affects of fear and suspicion in the aftermath of terrorist attacks in the United States on 11 September 2001. These affects of fear and suspicion were transnational in their provenance and enabled some people in the Western world to feel a strong sense of identification with the victims of these terrorist attacks: for instance, the French newspaper *Le Monde* ran a front page headline stating: "We are all Americans." Equally important, the affects of fear and suspicion that circulated after 11 September 2001 had the effect of demonizing racial and religious Others as potential terrorists: in many Western nations, this resulted in hate-based violence against those who 'appeared to be' terrorists and to their imprisonment and deportation.

Popular culture, then, is socially and politically consequential. Our subjectivities are constituted in the process of making sense of the world around us and in our interaction with others and, in many cases, making sense of the world entails engaging with it not just cognitively but, also, through affect. In capitalist and postcapitalist societies, these processes are refracted by media. Film, television, popular music, and mass market fiction constitute and represent the public realm in cognitive, moral, and affective terms. But these representations do not impact us as if we are blank screens – instead, 'they occupy and rework the interior contradictions of feeling and perception … they do find or clear a space of recognition in those who respond to them' (Hall, 1981, p. 232). Thus, although representations are neither all-powerful nor all-inclusive, they have material effects on how people see themselves and lead their lives.

Scholarly Perspectives on Popular Culture

Definitions of popular culture have shifted according to the disciplinary emphases of its students. Historians of early modern Europe (e.g., Peter Burke (1978) and Robert Darnton (1984)) stress how members of different classes created and participated in popular culture and, simultaneously, were shaped and constrained by it. These historians analyze the factors influencing the popular cultures of early modern Europe, chiefly, the rise of cities and the advent of printing. They supplement thematic analyses of books with information about audiences and, thus, aim at providing the context for the meaning and uses of books.

One of the foundational works on the relationship between capitalism and mass media is Max Horkheimer and Theodor Adorno's *The Culture Industry: Enlightenment as Mass Deception* (1944). Horkheimer and Adorno focused on how culture and the individual are 'produced' by the culture industry. They claimed that the culture industry's power lies in its ability to disseminate ideas and beliefs on a mass scale. They were concerned about how the management and control of leisure time and the socialization of the ego by the culture industry leads to a 'mass' culture that undermines the private realm.

The relationship between modern forms of popular culture and the growth of capitalism is also examined by some cultural studies scholars. Some of the most influential work in this area was produced (and has been influenced by) the Centre for Contemporary Cultural Studies at the University of Birmingham, UK. These scholars are concerned with how media shape dominant ideologies and discourses. Their central project is to examine the relationship between the production and consumption of popular culture and social axes of inequality, such as class, race, and gender.

Although cultural studies' earliest borrowings were from literary criticism, chiefly the work of Raymond Williams and Richard Hoggart, recently its primary focus has been on the practices of everyday life. The greatest debts of this genre of cultural studies are to Marxist theories of culture. Its basic premise is that cultural production often takes the form of commodities. Other important propositions are as follows: (1) popular culture is inextricably tied up with social relations; (2) popular culture can both enable social groups to define and realize their needs and reproduce asymmetries; and (3) popular culture is a terrain where social differences and struggles are articulated. These concerns reflect the influence of Gramsci on the ideological and popular struggles involved in the construction of common sense. In addition, some cultural studies scholars influenced by Lacanian analyses of film and television reconceptualize ideology in terms of how texts

construct subject positions. Others have rethought the role of ideology in popular culture in terms of Foucault's analyses of discursive practices. Breaking with Horkheimer and Adorno's assumption of the audience as a passive and undifferentiated mass of receivers, these cultural studies scholars conceive of audiences or consumers who actively 'decode' and interpret popular culture texts.

In addition to studying everyday practices, some cultural studies scholars also use semiotic methods of textual analysis. They treat cultural products as 'texts' to be 'read' according to interpretive strategies, including the literary analysis of narrative, semiology, and deconstruction. These analytical strategies reveal that literary conventions and forms have greater social and cultural significance than we might first suspect. For example, feminists have pointed to the place of fictional representations of romantic love in cultural constructions of femininity. Far from being 'mere' literary constructions, these representations play a crucial role in the constitution of dominant practices of gender and sexuality.

Anthropologists bring important theoretical and methodological insights to the study of popular culture because of their commitment to ethnographically analyzing the relationship between popular culture and other social institutions. Initially, mass media were neglected by anthropologists (exceptions include Bateson, 1943; Powdermaker, 1950) because they were deemed 'too redolent of western modernity and cultural imperialism for a field identified with tradition, the non-western and the vitality of the local'(Ginsburg, 1999, p. 297). Some anthropologists have insisted on foregrounding the *social practice* of media (Abu-Lughod, Ginsburg, and Larkin, eds.) and examine the cultural implications of popular culture through an ethnographic attention to the everyday practices and lives of producers and/or consumers of media.

Anthropological perspectives underscore that popular culture cannot be generalized across different historical and cultural contexts simply on the basis of the media apparatuses. Producers and consumers of media are, fundamentally, social and historical subjects and media are, primarily, cultural institutions that need to be studied in their concrete particularity. Hence, we cannot conceptualize relationships between popular culture and the social actors who engage its myriad texts in the abstract: neither can be studied outside their location in specific sociohistorical contexts. Several anthropologists have engaged in analyses of popular culture. These scholars, together with those who study the reception of media, carefully situate popular culture in the discursive and historical contexts in which it is produced and consumed. These studies undermine unilinear models of 'communication flows,' and foreground the importance of examining the specific conditions in which popular culture circulates.

Other scholars have examined how media have shaped our sense of the public. Drawing on and critiquing notions of the public sphere first articulated by Jurgen Habermas, these scholars have examined subaltern counterpublics and multiple publics, or have proposed notions of public culture as an alternative to those of the public sphere. Others have pointed to how gender and conceptions of intimacy play a critical role in how we think of the public. Many scholars foreground the role of transnational media in the formation of multiple publics. Far from proposing a dichotomous relationship between the public and the private, all these scholars assert that media blur the line between the two.

Popular Culture as a Lens for Studying Other Sociocultural Processes

Popular culture is a terrain where identities are articulated, negotiated, and consolidated. For example, class position might provide individuals with 'cultural constraints' and a common 'outer frame of meaning' (Darnton, 1984, pp. 6–7). A mutually influencing relationship exists between elite culture and popular culture. Popular culture also provides a site for the negotiation and articulation of class identities and other hegemonic discourses. Thus, in nineteenth-century India, Bengali elites took upon themselves the task of 'purifying' popular culture produced by working-class women: while their objective was ostensibly to 'emancipate' women of their class, their efforts resulted in the consolidation of their own middle- and upper-class identities through the marginalization of working-class popular culture (Bannerjee, 1989). At the same time that these interventions influenced (and were influenced by) hegemonic discourses of class and gender, they also became foundational to discourses of culture that were fundamentally nationalist.

The role of popular culture in mediating discourses of gender and sexuality has long been acknowledged. Two pioneering works in this regard are Laura Mulvey's *Visual Pleasure and Narrative Cinema* (1975) and Janice Radway's *Reading the Romance* (1984). Laura Mulvey examined how the cinematic forms and narratives of classic Hollywood film 'suture' viewers into 'spectatorial positions' that reinscribe dominant ideas about gender and sexuality. Mulvey's work provided feminist critics of popular culture with a paradigm for examining the role of mass media in the constitution of discourses of gender and sexuality. Janice Radway's work laid the foundation for studying the role of a specific genre of texts, romance fiction, in the constitution of discourses of gender and sexuality. Radway situated women's reading practices in their social relationships and everyday lives, and studied their interpretations of different romances in order to analyze what the books mean to their readers.

Since the publication of these works by Mulvey and Radway, the relationship of popular culture to gender and sexuality has been analyzed by scholars too numerous to cite. Some of the most noteworthy studies in this regard, however, come from scholars, chiefly anthropologists, who have examined media in non-Western contexts. These include the analysis of the relationship between popular culture, gender and sexuality in Japan (Allison, 1996), and television and notions of modern womanhood in Egypt and India (Abu-Lughod, 1993; Mankekar, 1999 respectively). The significance of these studies lies in their decentering of Eurocentric perspectives dominant in cultural studies, media studies, and feminist studies.

Some scholars have argued that the conceptualization of popular culture was itself engendered by the emergence of nationalism (Burke, 1978). Building on Benedict Anderson's insights about the role of print capitalism in the construction of nations as imagined communities (1983), several scholars have examined the role of popular culture in the formation of

national identity. For instance, diverse forms of popular culture, including tourism, exhibitions, and material culture and consumption, have enabled the constitution of the national imaginary in China (Anagnost, 1997). In some parts of the developing world, television has been consciously deployed to construct a 'national community': in Mexico and Venezuela, indigenous soap operas called telenovelas have combined entertainment with 'social messages' about development. In India, state-owned television was harnessed to the explicitly nationalist goals of development and national integration (Mankekar, 1999) and, furthermore, participated in the consolidation of an exclusionary and strident Hindu nationalism (Rajagopal, 2000).

Yet, at the same time that popular culture enables the constitution of local and national communities, some of its forms are inherently transnational. Thus, the telenovelas described above circulated not only within but across national borders in Latin America and were adopted as models for the television programs in India. In addition, the transnational circulation of popular culture has resulted in the creation of new forms of diasporic identities. The transnational circulation of newspapers, film, television programs relayed via satellite, advertisements, and mass market fiction have created, what anthropologist Arjun Appadurai has termed, 'mediascapes' (1996). Mediascapes 'refer both to the distribution of the electronic capabilities to produce and disseminate information … now available to a growing number of private and public interests throughout the world, and to the images of the world created by these media' (1996, p. 35). The boundaries of cultures and nations have thus proved to be permeable to globalized and transnational forms of popular culture. However, as scholars have argued for several years, globalization has not resulted in a homogenization of culture. At different historical moments, globalization has resulted in a recasting of 'tradition' and processes of creolization (Hannerz, 1996, pp. 67–77). Transnational popular culture thus forces us to revisit previously held notions of culture as bounded and systemic (Appadurai, 1996; Gupta and Ferguson, 1997).

In recent years, digital media have been critical to the further expansion of our sense of transnational popular culture. Digital media or 'new media' may alter previous conceptions of spatiality and temporality by muddling our sense of distance and proximity, the virtual and the actual. Scholars have now gone beyond *either* valorizing new media as liberatory and empowering *or* condemning it as divisive and oppressive. We have learned how the internet provides sites for arranging marriages; it is also a locus for the formation of hate-based collective identities. Online communities may offer a sense of solidarity to victims of child abuse; at the same time, the internet has also provided opportunities for child pornography and hate-based bullying leading, in some cases, to tragic consequences. Digital technologies may shift power dynamics to provide marginalized groups with access to representation. But, here again, we are also reminded that 'new media,' as much as 'old media' like television, radio, and film, are imbricated in existing power relations (Wilson and Peterson, 2002).

It is important to note that popular cultures generated by new media coexist with other media like film, television, and radio. Nevertheless, recent developments in new media studies also underscore that we may need to rethink previous assumptions about the relationship between humans and machines, the social and the technological, and organic and inorganic forms of life. Thus, for instance, digitization has compelled us to rethink migration and labor (as in the 'virtual migration' of call center workers whose labor travels even as their bodies remain in place (Aneesh, 2006)); electronic surveillance technologies and cyberwarfare have transformed how we think of national security; digital archives have changed how we think of privacy; and webcams and Ipods now seem to have extended our senses of sight and hearing (Balsalmo, A., 2008; Berry et al., 2003; Constable, 2013; Escobar, 1994; Ito et al., 2010; Kolko et al., 2000; Kroker and Kroker, 2008; Morse, 1998; Nakamura and Chow-White, 2011; Stratton, 2008; Tsatsou, 2009; Turkle, 2005, 2012). Furthermore, it is important to remember that even as the digital moves at the speed of light in the form of code, it is refracted by race, class, sex, and gender; conversely, domains of popular culture cohering around digital media compel us to revisit our assumptions about race, class, sex, and gender. Ultimately, digital popular cultures, like popular cultures of print or electronic media, are constituted through sociality even as they transform our sense of the social.

Popular Sexual Cultures in Western Europe (1930s to the Present)

Franz X Eder, Universität Wien, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article begins with general considerations about popular sexual beliefs and cultures in Europe since the 1930s. Then it shows how state interventionism, conservative family values, and commercial eroticization shaped the sexual culture during the late 1930s until the early 1960s. The 'sexual revolution' from the mid-1960s to 1980s is discussed in different aspects between liberalization of sexual mores and new forms of sexualization and regulation. Since the 1980s the western European culture is highly sexualized. Sex thereby has become a consumer product between negotiation, risk, and virtualization. After the sexual liberalization of the 1960s and 1970s and the gender revolution of the 1980s, the 1990s saw a radical change in relationship culture – matrimony decreased and long-term cohabiting partnership rose. The preferred sexual relationship is now one in which both partners communicate on an equal basis.

Popular sexual beliefs and cultures in Europe were subject to swift and, at times, radical changes during the second half of the twentieth century. New sexual images, norms, and identities affected peoples' erotic fantasies, sexual knowledge, and attitudes. During this period, changes in popular culture effectively became people's day-to-day 'lifeworld' experiences (Schütz and Luckmann, 2003). At the same time, the potential for communication increased, supported by the expansion of educational institutions and growing mass media that opened up yet further new sexual ideas, fields of knowledge, and images to an ever-increasing audience; the educational institutions reached out to a broader range of social classes; and the extensive distribution of mass media such as books, newspapers, and magazines, and the development of new media such as movies, radio, TV, and the Internet reached even more. Therefore, the second half of the twentieth century saw the term 'popular sexual culture' evolve to refer to a culture 'which is widely disseminated and consumed by large numbers of people' (Hinds, 2006: p. 163).

Media-based communication resulted in traditional procurers of values and knowledge – such as parents, teachers, and priests – loosing their pedagogic importance and being replaced by new knowledge informers – such as sex researchers, guidebook authors, politicians, writers, or movie directors. However, conventional understandings that had up to then been conveyed by 'closed' lifeworlds were not substituted altogether. Social and cultural traditions continued, passed down via gender-specific education, socialization within the peer group, value conveyance within the professional realm, and group-specific ideals relating to love, partnership, and family. More often than not, they were concurring with the generally advanced knowledge about sex and the eroticizing images displayed by the media. This 'productive' tension within the sexual culture of the twentieth century called forth relentless and emotional public debates, contributing in turn to changes in behavior and thought within just a few decades.

State Interventionism, Conservative Family Values, and Commercial Eroticization (the Late 1930s until the Early 1960s)

Propelled by the Great Depression of the late 1920s and the early 1930s, Western countries embraced conservatism while developing sexual morals and cultures. Franco's Spain, Salazar's Portugal, and Stalin's Soviet Union underwent a Puritan change. Fascist governments of Italy (as of 1922), Germany (as of 1932–33), and Austria (as of 1934), and subsequently of all countries occupied by the Germans, made sexuality an essential part of their ideological quest (Quine, 1996). Consequently, one's personal sex life was no longer a private matter but was turned into a topic of debate around nationalism and race. Supported by pronatalistic measures, the supposedly pure and 'high-grade' (Aryan) segment of the population was encouraged to expand. Measures included symbolic awards to women who 'joyfully' had given birth many times, tax benefits for large families, the displacement of women from the labor market, the reestablishment of men as heads of the family, and harsh penalty on contraception and abortion. In the long run, these measures failed to generate any substantial change in sexual conduct. Other countries, too, began to upgrade their public health departments and medical counseling centers, and as a consequence their medical competence.

The fascists' cult of the body made nudity socially acceptable, transporting it into racist, nationalist, and aesthetic concepts. Bodies 'steeled' by gymnastics and sports symbolized strength, discipline, and the eagerness to procreate, and at the same time allow for the publication of nude pictures without it being stigmatized as pornography. As a consequence, an inadvertent mass reproduction of nude photos took place decades prior to the 'sexual revolution'. The sexualization of images was, however, two-sided: the beauty of the pure body was counteracted by 'degenerate art' depicting undisciplined sexual craving; and the menacing art of lecherous Jewish, homosexual, and Black artists. The same applied to erotic glamour girls displayed in French magazines and in photos and postcards sold under the counter. In general, fascist regimes tended to assume a prosexual attitude as far as premarital and extramarital relations were concerned. Apparently, the image of the presumably sex-averse Nazi regime was one of the myths materializing in the late 1960s and 1970s in the wake of the so-called struggle to come to terms with National Socialism (Herzog, 2005; Eder, 2007).

The era's prostitution did, in fact, evoke ambivalence: On one hand, it was generally accepted that a man should occasionally frequent professional prostitutes, provided he did not contract any venereal diseases (VDs). On the other hand, this ubiquitous probability of infection made prostitutes a threat to

the whole population, not just families, and the military. In addition, homosexuals were seen as a menace to moral purity through their employment of seduction techniques and the ensuing 'contagion'. The fascist regimes' homophobia resulted partly from the problematic demarcation of homosocial and homoerotic male relationships within their own – usually unisexual – organizations. Homosexuality was suspected to be a contagious disease spreading rapidly within male and youth organizations. Consequently, threats of penalties, the banning of relevant magazines, and the policing of gay and lesbian subcultures, increased. Homophobia reached a state where neighbors, colleagues, and even family members volunteered to denounce suspected homosexuals. At the same time, during the 1930s, the Nazi regime utilized the population's antihomosexual resentments when attacking government critics; for instance, when employing political purges upon church representatives and aberrant party members after incriminating them to have committed homosexual offenses.

During World War II, restrictive attitudes toward sexuality were on the rise as distress and dearth left their mark. Contraceptives were difficult to obtain, abortion rates rocketed, and VDs spread. Married couples became alienated after long separations. Military officials therefore recommended sex during home leaves seeing it as essential to the troops' morals. Military brothels – often abusing women, mainly forced laborers, and concentration camp captives – served the same purpose. Women in general faced increasing sexual violence: countless forcible rapes were committed by members of the German Wehrmacht in their occupied territories (Beck, 2004) and by members of the allies, particularly the Russian soldiers, in Germany and Austria in 1945. These traumatizing experiences had dramatic effects on those involved but were hardly acknowledged after the war. Many of the women were scarred for life from the enforced physical and mental assaults, and their sex lives were permanently affected by the ordeal. Marriages frequently failed as women could not explain their feelings and experiences to their husbands or because some husbands considered the sexual assault to be conjugal infidelity (Kral, 2004).

Numerous voluntary sexual relations between soldiers of the NS Wehrmacht and local women took place in the occupied territories. German-occupied areas in western and northern Europe, for instance, remained largely undisturbed by acts of war until the allies' invasion and retention of 'civil life' meant that sexual contacts of occupiers with local women took place, as reported from France, Belgium, the Netherlands, and Norway. After the war, many of those women were seen as collaborators and labeled as 'Germans' whores'; along with their children, they were stigmatized and frequently attacked. Attitudes toward allied occupiers were similarly ambivalent. GIs, the soldiers of the US army, in particular represented a new type of man, who seduced women with offers of food and extra rations. They were popular with the local young women who, after years of wartime deprivation, wanted to have a good time; others acted out of sheer monetary need. At the same time, GIs gained a bad reputation in England. They were attacked for being 'overpaid, oversexed, over here' (Hall, 2000: p. 145), suspected of being the driving force behind the VD epidemic, and were blamed for the alleged moral decay of young women and their sexual permissiveness.

A 'sexual crisis' developed. Owing to the long separations, spouses drifted apart. Women had grown more independent, and men had returned changed or 'broken' by war trauma. Divorce rates increased as rapidly as did illegitimacy, abortions, and VDs. Couples, who were reunited, often lacked the contraceptives necessary for having sex without fear. From 1947, Beate Uhse, the founder of the future worldwide sex company, realized the situation and started distributing information on contraception in a brochure marketing the Knaus–Ogino temperature method; this enabled a woman (or women) to calculate her fertile and infertile phases.

Young people developed a craving for adventurous sexual experiences, while facing an imbalance in the ratio of women to men owing to the war's death toll in men. With the loosening of censorship, educational advice literature came onto the market supplemented with erotic magazines styled in the US manner; the latter depicted pinup girls that had been part of every Western allied soldier's field kit during the war (Hanson, 2004). Meanwhile, VDs lost much of their threat once penicillin was introduced after the war.

The evident liberalization of sexual attitudes during and after the war was confirmed by surveys conducted in several countries at the end of the 1940s. They revealed that contraception was by now widely used and premarital sex was indeed accepted, if only with prospective spouses. Opinions on abortion, prostitution, and masturbation varied, but people mainly remained antagonistic toward homosexuality. A healthy sexual relationship was now regarded as being essential to a successful marriage. Yet, in spite of these liberal tendencies, for the most, sexual activities remained more acceptable for couples who were already married.

Postwar 1940s and the early 1950s saw a clampdown in reaction to the perceived sexual chaos: The neoconservative (nuclear) family ideal was at the heart of this moral reconstruction. Sex manuals published clear definitions of a woman's role: Their job included being a willing and enthusiastic sexual partner. Sexual freedom was curtailed and sex became a quintessentially private and nonpolitical act. The sexual fidelity of a woman was a highly treasured value.

Premarital restraint and sexual integrity headed the Christian prescription for a future love match and a happy matrimonial life. Contrary to men, women were seen to be more emotional, eager to procreate, and sexually passive by nature. Among the approved sexual ideals for adolescents were virginity, restraint from masturbation, and a stable heterosexual orientation. In European countries, sexual education was regarded as the responsibility of the parents, but brochures and films gained territory as commercial interests increased (Martin, 2003: pp. 135–136). German and Austrian porn laws came out around 1950 aimed at preventing the distribution of 'pulpy and pornographic literature'. Marketing and distribution of contraceptives were subjected to strict regulations, resulting in soaring sales of 'discreet' ordering services.

Several 'sex problems' of the war and postwar period, such as sexually transmitted diseases and prostitution, became less significant in the wake of medical advance and the stabilization of the family system. And even though rates were somewhat higher than in the 1930s, the topic of illegitimacy and abortion also faded into the background. As economic prospects began to brighten, many illegitimate children, often conceived by long-time couples who had postponed marriage in the hope of a more stable economic future, were legitimized by fast

marriages. Homosexuality, on the other hand, largely remained an indecent topic, yet the predicaments of – mainly male – homosexual life managed to reach the public via press releases on sensational arrests and legal proceedings.

Homosexuals were seen as the antithesis of the heterosexual married couple; Finland's media became particularly concerned "when the issues of family, motherhood, and women's employment were also very much in the forefront" (Löfström, 1997: p. 33). The statements of medical doctors, psychologists, lawyers, and politicians reinforced prejudiced stereotypes, even in countries where they did not strictly prohibit homosexual acts. In France, homosexuals were blamed for refusing to procreate and were equated with Nazis and Arabs (Copley, 1989: p. 218). More open discussions were taking place in Britain with the establishment of the British Wolfenden Committee (1957), which suggested decriminalization of consensual homosexual acts among adults (over 21 years of age) and same-sex prostitution.

The 1950s and the early 1960s can be perceived as a period of conservative sex morals, yet they were also marked by a media-hyped boom of eroticism. A commercialization of sex took place in popular culture, particularly in the music and movie industries, as investors realized the potential value of sex. 'Elvis the Pelvis' and other rock 'n' roll musicians began to attract the attention of young people. 'Wild' dancing styles opened new opportunities to young men and women to express themselves more openly than to their parents from the frugal and sacrificing war generation. 'Sexy' movie idols, such as James Dean in 'Rebel Without a Cause' (1955), played angry and rebellious, and yet highly attractive young heroes. Bikinis and 'atomic boobs' adorned the female body on magazine covers. Beauty contests became the 1950s' platform for marketing and adapting erotic body ideals to national and regional styles. Smut and men's magazines such as 'Razzle' and 'Playboy' (1953) published articles along with pictures of pinups (including the famous 'Vargas Girls') in glamour shots. American-style movie, music, and youth magazines conveyed 'gossip' and fashion to youngsters directed at the new 'teen' market. Everyone who had the opportunity went to see one of the new scandalous erotic movies showing naked actresses. Françoise Arnoul shed her clothes in 'L'Epave' (1949) and 'Le fruit défendu' (1952), and Hildegard Knef stepped naked (if only for a couple of seconds) in front of the camera as an artist's model in 'The Sinner' (1950).

Parent's adverse reaction to the media's sex symbols made them all the more appealing to their teenage children and ensured their attraction to the forbidden erotic culture. When Ingmar Bergman's *Tystnaden* (The Silence, 1963) depicted scenes of masturbation and sex scenes devoid of love or affection, the media cried out in protest, yet few people resisted going and marveling at the sensation: Some 10 million spectators made the movie a great commercial success.

A Revolution, or: Catching Up on Liberalization (Mid-1960s to 1980s)

Sexual lives in (western) Europe had, in fact, been 'revolutionized' decades prior to the so-called sexual revolution of the late 1960s and the 1970s; public moral standards and attitudes merely trailed behind established practice. What we refer to as 'the sexual revolution' is therefore not so much a swift and radical change of sexual conduct as a culmination of a lengthy process. From the mid-1960s onward, this process was widely discussed in Western societies and within a few years had led to a liberalization of attitudes and sex-related norms. In a strictly historical context, therefore, one should perhaps refer to a sexual 'liberalization' than 'revolution'. Without doubt, the discourse on liberalization via media, politics, youth, and student movements contributed to convincing more and more people to adopt the new liberal approach, eventually making them standard. Yet the sexual liberalization's entire impact was not entirely revealed until the 1970s, when politicians succumbed and modified the provisions of the law that had been in force for decades or even centuries. The new sexual culture showed itself in continuously decreasing marriage and birth rates. In devout Catholic countries such as Italy, Spain, or Portugal, the 'sexual revolution' came a few years later. However, Spain, immediately following the end of Franco's dictatorship in 1975, was flooded by a radical sex and porn wave.

During the 1960s, rapid economic development saw the change from productive to consumption society that made 'sex' a positive asset of culture and society. For the first time people were able to forget the years of deprivation and poverty and turn their attention to consumption and experience. Even in countries most affected by the war, the economy turned from demand-oriented to supply-oriented – more goods and services were available than demanded. Marketing and advertisement soon utilized sex as a communication tool to support products' and media's competitive edge (Reichert, 2003: pp. 133–166). Although traditional sex norms of the Churches were still in place, certain laws were relaxed: Business investors quickly took advantage of the opportunities that had opened up to make money from trading in erotic and sex-related products. Meanwhile, while sex has still being widely considered a 'dirty secret' by their parents' generation, young people happily absorbed any information on the subject. Yet sexualization was not a phenomenon restricted to youth and student culture. It was widespread, having initially emerged among the working class and lower middle class before reaching better-off juveniles and students.

Furthermore, liberal attitudes were supported by political and democratic developments such as feminist and antiracism movements. Increasing individualization also had its impact, allowing people (young people in particular) to develop their own and very private living. This private space became more widely accepted as a realm where one had a right to pursue one's sexual pleasures (provided they were within the law). In some countries, several years passed before governments changed their laws and fell in line with popular practice. In Holland, it was the Catholic and Protestant clerics that advocated a positive approach to sex life and sexual questions regarding education or marriage – including contraception and divorce.

One of the prevalent factors propelling the change in attitude toward sexuality was, indubitably, the popularization of sexual knowledge provided in guidebooks and educational movies. They shifted attitudes from focusing on marital intercourse to an imperative to the pursuit of one's own individual

experimental experiences. Professional sex 'science' and psychiatry remained, for the time being, dedicated to sexual pathology, reaching but a small circle of interested intellectuals.

Schools also eventually opened up the topic for debate: Sex education classes were discussed for years before finally being put in place in the 1970s. This move also revealed the need to first educate the schoolteachers who were to teach the subject, not only the social and cultural aspects of sex life but also the biological ones.

From the middle of the 1960s onward, magazines depicting half-naked female bodies eagerly reported on various ways and practices of 'physical lovemaking'. At the same time, the first 'modern' educational movies were shown. From 1970, the commercial exploitation of the sexualized – mostly female – body served the basis for movies such as *Schulmädchen-Report* (*Schoolgirl Report*), viewed by some 25 million spectators all over Europe.

During the late 1960s and early 1970s the pornography laws were abolished. Denmark was the first to legalize the distribution of 'classical' erotic literature in 1979. Two years later, all the prohibitions of erotic texts, images, and objects were dropped. In October 1969, Copenhagen hosted the world's first 'erotic fair', attracting national and international – mostly male – visitors of all social classes. Sweden overturned its pornographic laws in 1971, and advanced quickly to be a dominant supplier of related products. By the middle of the 1970s, pornography was available to all adults in most other European countries.

Representatives of the new feminist movement criticized the sexual objectification of the female body, and objected to the pandering to men's power-obsessed domination fantasies. Nonetheless, the market for erotic and soft-core magazines such as the 'weekend magazines' flourished, and hard-core images and movies began to appear, concentrating on showing the sex act at the expense of a proper plotline. Television, now the leading medium during the 1960s, eventually fell in line.

'The pill' made a huge impact on popular culture. In 1962, the first hormonal contraceptive 'Anovlar' was sold in Europe. By the middle of the 1960s, advertising and press reports had generated sufficient publicity for the oral contraceptive to be prescribed and purchased on a larger scale. A survey from 1989 revealed that around 75% of all English women born between 1945 and 1959 were using the pill, lifting the threat of unwanted pregnancy from their sex lives (Cook, 2004: p. 281). For the first time, young women could take control of their sex lives without requiring their partner's support; the pill was also reliable, relieving much of the anxiety of unwanted pregnancy. Meanwhile, feminist movements voiced their concerns over the lack of surveys on long-term use and possible adverse reactions, and suggested that women had once again ended up with yet another burden of unshared responsibility.

The youth movement was another force propelling sexuality into public debate. Striving to confront their authoritarian parental generation and the capitalistic consumerism they represented, young people banded together to establish alternative lifestyles involving flower power, beat music, and drugs. They introduced the concept of 'free love', the message 'Let's Spend the Night Together' proclaimed by the Rolling Stones acting as the leitmotif for popular youth culture and their leading medium, rock music. The spirit of freedom in the Summer of Love (1967) was seized by the youth movement as the beginnings of a new time of sexual liberation with an expectation that a revolution of general social standards would follow. The most prominent example was Berlin's 'Kommune 1' who conveyed their criticism on society via sex scandals. 'Make Love Not War' was their motto, aimed especially against the Vietnam War. Wilhelm Reich and Herbert Marcuse supplied them with the theoretical ammunition to develop a sex-based explanation for the bourgeois repression of sexuality. According to these authors, liberalization of sex was mandatory in order to create a more just and nonrepressive society. The limitations of the youth and student movements were exposed by the women's liberation movement of the 1970s, who equated social dominance of men with phallic dominance in bed and put a noisy end to the 'Myth of Vaginal Orgasm'.

As a result of public debate, laws against abortion were abolished. In Germany, for instance, hundreds of women in a spectacular campaign of 'Stern' magazine (1971) admitted that they had had abortions, pointing out the uselessness of the law. In the wake of the protest movements and their exposure in the media, the laws were changed in various countries and abortion was permitted within the first 3 months of pregnancy or under special circumstances agreed by the doctors (GDR 1972, Austria 1973–75, Sweden 1974). On a practical basis, however, it took years to supply the required number of doctors and medical outpatient clinics sufficiently equipped to undertake the demands for abortion.

The 1970s saw the liberalization of regulations regarding family and divorce, both for contracting and dissolving marriages of two (heterosexual) partners based on their mutual consent alone, civil contracts were allowed, devoid of any religious ceremony. Gays and lesbians vehemently demanded legal and social emancipation with the 'Stonewall Riots' attracting considerable media attention: On 27 June 1969, for the first time homosexuals openly rebelled against police harassment and discrimination after a raid at the 'Stonewall Inn' located at New York's Christopher Street.

In western European countries, gays and lesbians made their voices heard in demonstrations and demanded change(s). Laws against homosexuality were annulled, but different regulations concerning the age of consent, matrimony, hereditary, and adoption remained unchanged for decades to come. The cultural identity of gays and lesbians, however, did change during the 1970s. Traditional role concepts of effeminate men and masculine women faded to be replaced by so-called normal homosexuals who increasingly adopted their own genders' identities. Most homosexual couples now socially positioned themselves akin to heterosexuals, and formerly marked age differences between same-sex couples diminished.

Comparative studies on German students confirmed the shifting of attitude toward homosexuality. Between 1966 and 1981, they increasingly tolerated homosexuals while their own heterosexual orientation became more fragile. At the same time, heterosexualization became further entrenched in the 1970s and 1980s, seen in decreased homosexual contact during adolescence (Schmidt et al., 1998). This was a result of coeducation and better sex education. All those having sexual

contact with another person of the same gender were now forced to contemplate the possibility that they were homosexual and would be subject to stigmatization as homosexual.

In general, as far as sexual behavior and attitudes of 'conservative' groups were concerned (of which students were a part), they both changed rapidly. As has been the case with young working class members during the 1950s and 1960s, premarital sexual intercourse now grew to be standard among other classes, and the number of sex partners and frequency of intercourse increased. The employment of a variety of sex techniques became a sexual imperative just as did the acceptance of masturbation prior to and during partnership or matrimony. This progress was most obvious among women. Premarital virginity ceased to be regarded as a virtue; young people mostly rejected the sexual double standard as a relic from their parents' generation. Supported by the feminist movement, sex guidance literature, and the media, more and more women actively demanded that their specific sexual desires should be satisfied.

Sex between Negotiation, Risk, and Virtualization (the 1980s to Present Day)

As a result of liberalization in the late 1960s and the 1970s, sex was soon fully integrated into the commercial supply of the Western market. Products and services were sold in the media as sexual promises. This oversexualization rapidly reduced the effect of sexual stimuli forcing the advertising industry to push back the barrier of what could or should be explicitly depicted (Reichert, 2003: p. 364). Visual sexual stimulation was easily obtained in the rapidly expanding market of erotic and pornographic magazines and movies, offered for sale at every kiosk or video store's adult section. This gave birth in the 1980s to a feminist movement named PorNo, fighting against pornographization of the female body and the accompanying violent sex fantasies. At the peak of the sex war in the middle of the 1980s, the battles involved "the regulation of pornography, the scope of legal protection for gay people, the funding of allegedly 'obscene' art, the content of safe-sex education, the scope of reproductive freedom for women, the extent of sexual abuse of children in day care centres, the sexual content of public school centers, and more" (Duggan and Hunter, 1995: p. 1). Alternatively, 'porn for women' voted for a different kind of eroticism and pornography that would cater to the needs of women.

A satisfactory sex life had now come to be a requirement for (post)modern men and women. Terms such as 'performance', 'innovation', and 'technique' entered the sexual arena, aimed at improving one's own and one's partner's pleasure. Sex manuals suggested remedies for impotence and suggested on how to work on lack of sexual interest. Therapists and sexual medical doctors offered their services, and in the middle of the 1990s, Viagra came to the aid of those suffering from impotence. Those who did not manage to act out their fantasies and desires with a lover or sex partner would soon find substitutes in new technology such as telephone or the Internet sex. Increasingly, masturbation came to be regarded as a separate autoerotic sexual realm offering uncomplicated sexual satisfaction or simply relaxation.

In the face of affordable; easily obtainable; and, most importantly, safe contraceptives, sex was no longer tied to procreation. Meanwhile, new reproduction technologies (such as *in vitro* fertilization) detached procreation from sexual desire. Sexually transmitted diseases lost some of their threat owing to effective remedies. During the 1980s, however, AIDS became the new fear but was then thought to affect only a marginalized minority. Moralizers even claimed the 'gays' pest' to be a divine retribution for the promiscuity of homosexuals. Nevertheless, the AIDS panic only held up the increasingly liberal approach to homosexual men and women for a short while. Intense coverage of homosexuality in the media even opened up new insights into the social and relational cultures of gays and lesbians – with it came an increase in tolerance and acceptance. During the second half of the 1980s, it became evident that unprotected heterosexual intercourse had led to a rise in the spread of VD, putting an end to sex without worries and unprotected sexual liberty.

During the 1990s and the early twenty-first century, horrifying cases of pedophilia, child pornography, and sexual murder of children were exposed. Although the number of such cases had not increased – most assaults on children still occurred within the circle of family and acquaintances – the number of occurrences that were uncovered did increase, mainly owing to a higher sensitivity to these offenses. The highly emotional media coverage did, however, open the debate on age of consent and possible sexual dependencies between adults and children/adolescents. For some groups of migrants, sexual liberalization and sexualization went beyond their realms of tolerance that were defined by their traditional cultures' approaches to gender and sexuality matters. Violent assaults on the members of the gay community were reported from some of the new EU member states, where after 1989 latent resentments erupted as new homophobia.

In the 1990s also for adolescents and young adults, solid relationships and sexual fidelity grew more important, again as a reaction to a culture that had abandoned traditional sex morals and replaced them with negotiation or consent morals (Schmidt, 1996). The desire to experiment in promiscuous relationships was increasingly replaced by a need for closeness and safety in a relationship. Now also the male youths increasingly connected sex to love and emotional ties and young women and girls demanded sexual pleasure more actively (Sachdev, 1993: p. 105). Using contraceptives was by now commonplace, yet first sexual contacts often still took place without protection, mainly due to embarrassment. In comparison with the sexual 'revolutionists' of the 1960s and 1970s, both men and women had come to perceive sex as a rather nonmythical and undramatic part of life, with no requirement for liberations or attachments to a political Utopia. This does not necessarily imply a sexual counterrevolution. The rigid attitude that had prevailed prior to the sexual liberalization never reestablished itself (McLaren, 1999: pp. 193–205). But in comparison with the liberal 1970s, some people displayed less tolerance to promiscuousness, to premarital and extramarital sex and homosexuality. "This ending of liberal advance might reflect a homeostatic cycle of reform or a reaction to problems created by liberalism in

general or sexual permissiveness in particular (e.g., increases in sexually transmitted diseases and non-marital births, possibly a desire for commitment rather than casual, recreational sex, etc.)" (Smith, 1994: p. 91). In Europe, the fueling of 'sex panics' repeatedly proved useful in introducing neoconservative and restrictive moral standards to everyday political discourse (Irvine, 2002).

The mass production of sexual cultural images and texts has had the effect of blurring gender and sex identities. Beyond polarized heterosexuality and homosexuality, there exists a wide range of sexualities today: hetero-, homo-, and multisexuals, androgyny, queer, and transgender sexualities, and so forth. Homosexual desire is widely accepted within the 'normal' range of sexualities – which is one of the reasons why sexuality has ceased to be a suitable basis for the constitution of a specifically gay or lesbian identity. According to today's confessional TV shows, everybody should or could be a little 'perverted'. The fetishizing of images of sex has not stopped at normalizing perversion. Currently, the Internet offers a conglomeration of diverse sexual practices, some of which, only a few decades ago, would have been subjected to penal law or, at the very least, investigation by psychiatrists. Furthermore, intimate bodily contact had been replaced by cybersex, the autoerotic pleasures of steel prostheses nipple claps, and machine-generated stimulation such as the Sybian (a masturbatory device for women), but such cold technology failed to take hold.

After the sexual liberalization of the 1960s and 1970s and the gender revolution of the 1980s, the 1990s saw a radical change in relationship culture – matrimony decreased and long-term cohabiting partnership rose. The preferred sexual relationship is now one in which both partners communicate on an equal basis (Giddens, 1992). Whether the relationship endures or not is influenced by mutual compatibility; which includes as a central factor; excitement, and satisfaction in one's sex life. As was the case in the 'romantic love' partnership of the eighteenth and nineteenth centuries, sex is now being integrated into the overall vision of a loving relationship. Instead of gaining only satisfaction in sex, a rounded loving relationship is being sought – yet sex is only one component of consumption, leisure, and individualism, an everyday experience along with many others. But the egalitarian, emotion-oriented, and soothing sex ideal misjudge vital constituents of sexual desire, such as difference in power relations and sexual tensions, and this may be one of the reasons why the sexual desire decreases instead of increases (Sinfield, 2004). Also, in most Western nations, criticism of sexual liberalization is increasing, with increasing authoritarianism eradicating freedoms gained since the 1960s and 1970s. Recent surveys have revealed that the number of people who are dissatisfied with their sex lives is rising – possibly a result of the growing gap between the media produced ideal, in all its glossy variations; and the unvaried everyday bedroom practices between spouses or partners. Compared to the other increasing differentiations in the world of consumption, Western capitalism has not diversified the average citizen's sex life, but restricted it (Hekma, 2005: p. 220): In the past two decades, normalized heterosexual monogamy has gained momentum, leaving promiscuous, homosexual, or prostitutive sex practices far behind. Prior to the 'sexual revolution', Europeans practiced sex in every way they pleased regardless of the law or moral reprobation. Now, it seems, the highly sexualized Western contemporary culture ignores the practices and forces us to make use of whatever sexual images and fantasies are available to us.

Population Aging: Economic and Social Consequences

Abstract

Demographic aging is a modern phenomenon: never before has there been a society that was so old, although within societies there were some old individuals. As of now, all societies will become old because they control both their mortality and fertility; they will be characterized by demographic transition and as a result, demographic aging. This change inevitably brings demographic and socioeconomic consequences. To be properly managed, they must be empirically determined and rationally studied, because the aging of populations is one of the great achievements in the history of civilization. Increasing numbers of people are reaching retirement and old age, and their relative weight in the population will be greater than ever before. The costs of health care and pensions will increase and their method of financing is a concern to many. In countries that do not have social security systems, innovative systems will have to be established, and in those that do, in-depth reforms will be required to insure that beyond traditional solidarity, we secure for the coming generations a degree of intergenerational equity.

The notion of aging is quite natural for human beings: from the age of reason, we understand that with the passage of time, every living thing ages and finally dies. Young children experience this with their goldfish or dog, adults with their parents, and old people with their friends. By analogy, we apply the notion of aging even to nonliving things: for example, as a car deteriorates, we say that it is getting old and eventually we relegate it to the scrap lot. Although a good wine may improve with age, in the end it becomes undrinkable.

From the individual, the notion of aging is extended to the group formed by the individuals: thus, we speak of an aging fleet of cars or an aging population, meaning that the average length of life of the entire group of these individual units changes with the passage of time (*see* Ecology of Aging). However, unlike the case for the individuals making up the group, the group itself is able not to age, or even to get younger. This is the case for human populations. For them, the aging process is strictly structural, not biological. The decay generally associated with the aging of individuals should not be assumed to apply to aging populations.

Population Aging: A Modern Demographic Phenomenon

A population changes through the interaction of the fertility, mortality, and migration of its members. In recent centuries, we have witnessed remarkable changes in human fertility and mortality, which, uncontrolled since time immemorial, had always been high. In the past, there was a 'natural' fertility and mortality, and population numbers throughout the world were relatively low. Eventually, people found ways to reduce first mortality and then fertility, after a certain time lag. In theoretical terms, this historical process is known as the demographic transition (Chesnais, 1992). During this process, the population grows at a higher or lower rate, depending on the extent of this time lag. At the end of the process, according to the theory, both fertility and mortality are low and the population stops growing. But an inescapable law of demography says that a population either grows or it ages (Coale, 1987). As all populations around the world have reduced or stopped their growth (United Nations, 2011), they are all bound to age. In some countries the fertility level is well below the replacement level, and thus their populations will decrease unless they experience in-migration, a possibility not foreseen by classical transition theory.

There are several ways of measuring the aging of a population. Instinctively, one could say that a population is aging if the average – or median – age of its members as a group increases over time. Alternatively, one could look for an increase in the proportion of old people in the population. But at what age does a person become old? We do not want to enter into a debate over the exact threshold of old age or retirement, but for purposes of illustration we will use the percentage aged 60 and over in the population (*see* Age Stratification; Age Structure). To avoid delving too far into the past, we will restrict our discussion of demographic aging to the period from 1950 to 2100.

During the twentieth century, the growth in the number of people aged 60 and over in different parts of the world was relatively small, and there were roughly as many people old (according to this definition) in more developed regions as in less developed regions. However, from now until 2100, this number will grow spectacularly, mainly because of the increase in less developed regions (**Table 1**). But if we look at the proportion of people aged 60 and over in the population as a measure of demographic aging between 1950 and 2100 (**Table 1**), we see that the situation differs greatly from one continent to another. Africa will remain young while the more developed regions as a whole will have a bit less than one-third of their populations in the 'old' category. Asia will age at an increasing rate: in 2100, it will have near 1500 million people aged 60 and over. This is half of the world's elderly population.

In the industrialized regions, the process of population aging is relatively slow, but in developing regions it will be more intense and rapid. This can be clearly shown by a comparison of Canada and the BRICS countries, a group of emerging economies formed by Brazil, Russia, India, China,

and South Africa (Laïdi, 2012) (Figure 1). In 2100, BRICS countries will be world leaders in demographic aging with almost 930 million people aged 60 and over. This is more than 30% of their total population.

In the face of globalization, the changes occurring over this century will give rise to a number of socioeconomic issues that would not have made themselves felt if population aging affected only the currently industrialized countries. There will be both demographic and economic and social consequences for our societies.

Demographic Consequences

As is easily demonstrated, in the early stages of the demographic transition aging is much more the result of a decline in fertility than in mortality. When mortality declines from a high level, it is primarily early deaths that are eliminated, in particular deaths of children and young adults. The result is a younger (not older) population, as was seen in Africa between 1950 and 1975 (Table 1).

But when life expectancy is already very high, as is the case now in industrialized countries, mortality becomes an

important factor in demographic aging. If mortality is low and decreasing, we get a double effect. First, increasing numbers of people reach the old age threshold – because of lowered mortality before that age. Second, people live for increasing lengths of time beyond this threshold – owing to a continued decline of mortality at old age (Shumanthy et al., 2012). The main consequence of this development is that old people no longer form a homogeneous group: we now have the young old, who generally are in quite good health, and the oldest old, who generally are more dependent for income security and health. Thus, we have moved from having three main lifecycle stages to four. There is a new third age that extends from retirement to the oldest-old stage. This is an entity that never existed before in human history (Laslett, 1989). Another important feature in mortality changes in many societies has been an increased mortality gap between men and women. Even if attenuated in the present century (Avdeev et al., 2011), very frequently old people in these societies are and will continue to be primarily old women.

Like any other population, the elderly population is subject to a process of incessant inward and outward movement of cohorts. In most industrialized countries the incoming generations will be clearly differentiated with respect to their numbers and their characteristics. The generations now entering retirement are the baby boomers born after World War II. They will be followed by the baby busters, who are far less numerous. These generations, particularly the women, will have characteristics very different from those of today's old people (Légaré and Ménard, 2007), especially in terms of education.

The changes in the age structure of our societies will cause major realignments that affect not only the elderly but the entire population. In terms of health and financial security, will old people be more independent or more dependent than before? The increasing presence of very old people tends to suggest dependence, while the characteristics of the future younger elderly appear to suggest greater autonomy. Will the younger adults, who are far less numerous than the baby boomers, be willing to pay for a golden twilight for tomorrow's seniors? We now turn to these questions in the following sections.

Economic Consequences

The Aging Process and the Working-Age Population

At the beginning of the population aging process, a standard age pyramid shows the population cohorts by age increasingly reduced by mortality. As the process gradually proceeds, positive impacts on the working-age population appear. The decline in mortality eliminates early deaths and increases population numbers. Then, as the effects of fertility decline come to the fore, cohort size is increasingly reduced. When mortality improvements lead to significant reductions in old-age deaths, the members of the retired cohorts become as numerous as, and sometimes more numerous than, those of working-age cohorts. The pyramid changes into a top and finally into a cylinder. This means that at the end of the aging process, all generations are of approximately the same size except for the very old. This process is reflected in the variations of what are commonly called the dependency ratios, one of which is the ratio of people aged 65 and over to those aged 19–64. Unfortunately, the use of the adjective 'dependency' may unduly give an impression of economic dependence. These indicators are merely indices of the age structure and it would be more appropriate to speak of demographic dependency ratios (*see* Age Structure).

In studies of aging we frequently find the members of the working-age population equated to actual workers. While in the past this was true for men when their labor force participation rate was close to 100%, it is now less so, in particular for women. To assess the economic impacts of aging and our ways of dealing with them, we needed to take into account not only population numbers, but perhaps more importantly, labor force participation rates and worker productivity (OECD, 1998). If the shift from agricultural to industrial societies had great impacts on the world of work, the shift to aging postindustrial societies will have an equally great impact. This is particularly true for the change in the rate of labor force participation by women and by older workers.

The radical decline in fertility and otherwise changing family arrangements has freed women from a myriad of family duties and made them available for increased participation in the paid labor market. The women's liberation movement also contributed to changes in attitudes and women are becoming increasingly independent, not only at working age, but also, and perhaps especially, during retirement.

One of the corollaries – and achievements – of the development of industrial societies has been the right to retirement and associated pensions. In the second part of the twentieth century, we have witnessed a decline in the labor force participation rate of older workers, along with a systematic decline in the age of leaving the labor market. This ever-earlier retirement from the labor market has now been reversed. As life expectancy increases, especially at old age, and as the time spent taking education is extended, the life segment in retirement is growing longer and the segment in which one works is getting shorter. When a large and growing share of the costs of social security, including pensions and health insurance, is borne by those who work, some adjustments must be considered. It is not possible to maintain contribution and benefit levels and, simultaneously, to bring down, or even maintain, the age of access to benefits.

There is a need for greater flexibility, both in wages and responsibilities for the population approaching retirement. For older workers, one should consider a gradual progression from wages to pension income, perhaps following a normal rather than S-shaped curve. This may call for a change in attitudes, not only among the workers themselves but also among employers and trade unions.

Solidarity among generations presupposes a minimum of equity between groups. When social security programs in the industrialized countries were reorganized after World War II, both the population and the economy were growing: the populations were young. Pay-as-you-go financing did not create any visible problems, and it eliminated some perverse effects of funded programs, many of which had collapsed in Europe during the Depression and the war. In aging societies – particularly those which have experienced a large baby boom followed by a baby bust – a hybrid system combining pay-as-

you-go and funded elements is likely to be more equitable across generations.

At present, the labor market is undergoing major changes. Workers will no longer hold full-time jobs for life the way they did previously in industrial societies. New workers will enter the labor market later in life. They will hold part-time jobs with varying employers, more often and possibly for a significant part of their working life, or be self-employed. From time to time they will have periods of unemployment or of retraining. Moreover, such patterns, which formerly applied mainly to women, will now apply to men as well. Consequently, retirement systems based on previous labor market participation and involving individual employers are subject to in-depth revision. In addition, one should take the value of unpaid work into account. In particular, work performed to raise children or to care for aging parents needs to be recognized.

An Aging Society: A Burden?

Because population aging is equated to individual aging all too often, one tends to highlight problems for aging societies, in particular problems related to the costs of health and pension programs for the elderly. On this subject some issues need to be clarified and some myths should be dispelled.

First, the situation of old people in most countries has improved greatly largely as a result of post–World War II social programs. There have even been hard economic times when their situation has deteriorated less than that of younger people.

Second, health and pension costs will certainly continue to increase in aging societies, but at what rate will this happen? With regard to health Zweifel et al. (2004) have shown that increases in medical costs are more closely linked to the number of old-age deaths than to the size of the elderly population, and the number of old-age deaths is increasing much less rapidly than the size of the elderly population (Légaré et al., 2006). The same is not true for pensions, whose costs are linked directly to the number of old people. However, one should not forget that retired people also pay taxes, both on their income and on consumption. As people age, their material needs (other than those related to health) decrease, however, and this might be reflected in their pension requirements.

Third, although incomes are on average lower at old age than at other ages, the elderly often hold a large share of the collective wealth through their assets, in particular by owning of their dwellings (*see* Intergenerational Solidarity).

In brief, far from being an impediment to economic development, elderly people in aging societies can sometimes serve as an important actor if not the engine of such development (Dirn and Mendras, 1984).

Social Consequences

Increasingly, the group of old people is not homogeneous with regard to health status and wealth, and this has numerous consequences for their life-style. First, let us recall that to a large extent the world of the elderly is a world of old widows. This feature has become increasingly prominent over the twentieth century, as excess male mortality has grown while the difference in age at marriage has remained stable. In addition, the twentieth century has been characterized by the quest for greater independence at all ages. Old people in industrialized countries prefer to live alone if they do not live with their spouse, particularly when they are in good health. But this choice does not necessarily imply isolation. Alternatively, living together with people other than one's late spouse may become a strategy for dealing with financial or health problems, perhaps as a stage that precedes institutionalization.

Multigenerational households are much more common in less industrialized countries, mainly for cultural and economic reasons. We can only wonder what will happen in the future in these societies. In a context of rapid urbanization and scarcity of dwellings, there will be an acceleration in aging following the sharp decline in fertility. With its one-child policy, China is a particularly poignant case. Demographic constraints may become apparent as daughters and daughters-in-law become increasingly less numerous and less often available to take care of old parents.

In societies with low mortality (or equivalently, long life expectancy), early deaths are reduced to a minimum and are usually related to lifestyle rather than caused by exogenous diseases. This produces a great deal of interest in the population's health status, and public health policy objectives may concentrate on insuring quality of life for the aging population more than on preventing early adult deaths. The focus moves from mortality to morbidity, from life expectancy to healthy-life expectancy (Robine and Cambois, 2013). By means such as surveys on seniors' functional capacities, it is possible to identify impediments to independent existence and to develop policies that will minimize the adverse effects of biological and social aging.

Such policies are centered on support networks (*see* Age Policy). Assistance provided to old people may come from professionals hired by the state, the community, or private enterprise. Alternatively, they may be offered by the family, friends, or neighbors. The expanding need for services provided through such formal and informal networks is an increasing source of concern. For the informal networks, the many changes that have occurred in family structures leave future prospects unclear; for the formal networks, it is mainly the cost that worries public policy makers. In this picture one should not forget that seniors are not only receivers of assistance, but very often also providers.

Conclusion

Some believe that the twenty-first century will see the emergence of intergenerational conflicts similar to the gender conflicts of the twentieth century. Major transformations of the population age structure have altered the ratio between the retired and the working population and will continue to do so. In addition to solidarity among generations, any reforms to social security programs taking account of the new demographic reality need to aim to promote intergenerational equity. For this purpose, we have seen the development of new measurement techniques, known as demographic accounting (Auerbach et al., 1999). Even if not yet often applied, by making use of individual-level data and by making adequate

long-term projections we will be able to benefit from these new methodologies.

In conclusion, we observe that for centuries, life in all its forms was regulated by nature. Gradually, human societies became able to control their destiny by largely controlling their mortality and fertility. This resulted in great changes for the societies, and in particular it accelerated their aging. The fact that most now live to old age and that our populations progressively age can only be regarded as great cultural progress (Légaré, 2005). However, like all progress, individual and societal aging must be managed skillfully. Moreover, we are in the midst of a process of shifting control from society to the citizen (Légaré and Marcil-Gratton, 1990). Decisions concerning demographic behavior, like whether or not to get married, whether to have children, how many and when, whether to leave an existing marriage and contract another one, and so on, are now made on the individual level more than ever before. In a world where centenarians will become rather common, people will doubtless also want to have a say on the timing of their departure from life (Légaré and Marcil-Gratton, 1990).

Population Change in the Former Communist States of Europe and Asia

Timothy Heleniak, George Washington University, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The 29 former Communist states of Europe and Asia underwent significant demographic change along with the political, economic, and social transitions during the 1990s and 2000s. This included steep declines in fertility, increases in mortality, and large-scale migration including large flows of refugees and internally displaced persons. These demographic trends lead to declines and rapid aging of the population of most countries in the region. In contrast to global population trends, most of the countries in the Eurasia region are projected to decline significantly in the future.

Introduction

The 29 formerly Communist, formerly centrally planned states in Europe and Asia (Figure 1) have undergone considerable economic, social, political changes over the past two decades which have had significant demographic impacts on these countries. This group of countries were once referred to collectively as the 'transition states,' because of the transitions they underwent starting in the late 1980s with the symbolic collapse of the Berlin Wall (World Bank, 1996). This consisted of three different transitions: an economic transition away from centrally planned economies toward market economies; a political transition of increased pluralism and control by lower levels of government marked most notably by the breakup of the Soviet Union, Czechoslovakia, and Yugoslavia, increasing the number of

Figure 1 The Eurasia region, 2010.

states in the region from 8 to 29; and a social transition toward more liberal societies.

While they share in common a legacy of at one time being part of the Communist block, they differ considerably in the degree and length of time that Communism influenced those societies. More importantly, they differed considerably in their levels of development while under Communism and have diverged even more so in the post-Communist period. They have also embarked on divergent political paths with some countries joining the EU and others becoming dictatorships. There is also considerable demographic diversity among these countries in terms of population size and growth and their stage of demographic transition. However, they are treated together because of their shared historical legacy. As is shown in this article, this shared legacy has resulted in the countries in the region combining demographic characteristics of both developed and less developed countries.

The article begins by examining the overall population change in the former Communist states during the two decades from the beginning of the economic, political, and social transition around 1990 to 2011. It then discuses the components of population change – fertility, mortality, and migration. A final section looks at the implications of the recent demographic trends and projections of the population of the countries in the region. For lack of a better term, Eurasia is used to describe the region, understood here as the current 29 former Communist states in Europe and Asia (Kosovo's independence is not universally recognized and given its recent independence, data are not always available). The year 1989 is chosen as the first year in many of the tables because it is the year of the last population census conducted in the Soviet Union. There are data issues in many countries in the region owing to the breakup of the three federal states and the necessity for all to make the transition from monitoring social and economic trends in centrally planned economies to market economies.

Population Change in the Transition States of Eurasia

Over the past two decades, there have been large differences among the Eurasian countries in their rates of population change and in the relative contribution of natural increase and net migration (Table 1). Over the past two decades, the global

population increased by 30%, with less developed countries increasing by 36% and more developed countries increasing by just 8%. The Eurasia region as a whole decreased by 2%, thus bucking a global pattern of population increase.

The populations of the Central Asian countries of Turkmenistan, Tajikistan, Uzbekistan, Kyrgyzstan, and Azerbaijan increased the most among Eurasian countries, with rates near or above those for global population growth and the growth rate for less developed countries. Nine Eurasian countries – Albania, Ukraine, Bosnia-Herzegovina, Georgia, Estonia, Moldova, Lithuania, Bulgaria, and Latvia – had population declines of 10% or more over this period. Those countries in the Eurasia region which grew the fastest did so because of high rates of natural increase due to their younger age structures. Most also had high net emigration. Those Eurasian countries which had large population declines usually did so because of a combination of both natural decrease and net emigration. One exception is Albania which continued to have high natural increase but declined in population size because of large-scale emigration of more than one-third of the population. The significance of migration as a component of population change is evidenced by 13 countries having had emigration of more than 10% of their populations (Bulgaria, Montenegro, Estonia, Kyrgyzstan, Latvia, Lithuania, Tajikistan, and Kazakhstan) and another five when had emigration of more than 20% (Armenia, Bosnia-Herzegovina, Moldova, Georgia, and Albania).

There is a high correlation between level of economic development and being further along on the demographic transition and the Eurasian countries are at quite different stages of the transition. In 1989, Tajikistan, Turkmenistan, Uzbekistan, Kyrgyzstan, Azerbaijan, Albania, Armenia, Kazakhstan, and Macedonia could be classified as being in the second or third stage of the transition with high birth rates and low death rates leading to rapid population growth. Large portions of the region's population were in countries in the fourth stage where births only barely exceeded deaths or were roughly the same and population growth was slow or declining.

By 2011, with the steep transition-era population declines there had been some shifts among many Eurasian countries in their place along the demographic transition. In the same group of Central Asian countries births exceeded deaths and their populations continued to grow, albeit at much lower rates. In most countries in Eastern Europe, deaths and births are about equal so the populations in those countries have stabilized or are declining slowly (often because of out-migration). In Russia, Ukraine, Belarus, Hungary, Bulgaria, Latvia, and Serbia, deaths exceed births by considerable amounts leading to population decline. Demographers have recently begun to discuss a fifth stage of the demographic transition or a second demographic transition. This is characterized by very low fertility rates, high rates of non-marriage and non-childbearing, and high rates of non-marital childbearing. Many countries in Western Europe and a number of the Eurasian countries are in this situation.

Fertility

While the high mortality rates in many countries in the region have received the most attention of scholars examining demographic trends, it is actually the low fertility rates and steep declines during the 1990s which have had the largest numeric impact on population change. Prior to the economic transition, the social welfare system in the Eurasia region was decidedly pro-natalist with long and generous maternity benefits and significant state support for early child care and education. Contraceptive prevalence was low by international standards and abortion had become the primary means of fertility regulation in nearly all countries in the region. Marriage and childbearing were nearly universal. The pattern over large portions of the region was early marriage and childbearing, followed by subsequent abortions of subsequent pregnancies (David, 1999).

In 1989, much of the population resided in countries where the fertility rate was at about replacement level as many women had settled into a two-child pattern as the norm. Fertility rates in the Caucasus (Armenia, Azerbaijan, and Georgia) were slightly above this between two and three children per woman. Fertility rates in Central Asia and Albania were the highest between three and five children per woman. With the economic transition and steep economic decline in the 1990s and changes in the social support system, fertility rates declined in all countries in the region and in most by large amounts. The fertility rate in those Eurasian countries with rates of about replacement fell to rates of between 1.1 and 1.3 children per woman in the late 1990s, levels demographers call 'lowest-low' fertility (Kohler et al., 2001), and early 2000s before recovering somewhat in the late 2000s (**Table 2**). A number of Eurasian countries have fertility rates which are among the lowest in the world. Fertility in the high-fertility Eurasian countries of Central Asia and Albania have also declined by about 1.5 children on average. In 2009, only Azerbaijan and the five Central Asian countries had fertility rates above replacement level. Thus, in Eurasian countries encompassing about 85% of the region's total population, the fertility rate is well below replacement level and is not expected to increase back up to that level anytime in the foreseeable future. This trend, coupled with already older populations and a declining number of women in the childbearing ages, will inevitably lead to population decline across much of the region.

Many observers attribute the transition-induced economic declines across the Eurasian region as the reason for the steep declines in fertility. While that fact is certainly a contributing factor, there are other aspects of social change that have contributed to the decline as well (Brainerd, 2007). The changing role of women and circumstances of child rearing were also contributing factors. The proximate determinants framework can be used to analyze factors influencing changes in fertility across the region over the past two decades (Bongaarts, 1978).

The number of marriages across the region declined by 28%, from 3.6 million in 1989 to a low of 2.3 million in 2000, with the decline being universal across all countries (Heleniak, 2010). This had a large effect because most births still occur within marriage. Modern forms of contraception were not a priority in the region during the Communist period and since 1990, there has been a universal increase in contraceptive prevalence rates across all countries for which data are available. The Soviet Union

was the first country in the world to legalize abortion and as a result, an abortion culture developed where it was an acceptable means of fertility regulation with little moral stigma attached and little public opposition. The number of recorded abortions fell from 7.2 million in 1989 to 2.3 million in 2007, a two-thirds decline. The decline was universal across all countries in the region. In spite of this decline, abortion rates in some Eurasian countries remain among the highest in the world. These factors have caused the number of births in the region to decline from 6.9 million in 1989 to a low of 4.3 million in 2001 before increasing somewhat to 5.5 million in 2009.

There has been a shift in the patterns of childbearing in the region, with later marriage, later childbearing, and higher shares of birth outside of marriage. There has been a shift in the relative contribution of women at different ages to the overall fertility with women aged 25–29 now having more births than those aged 20–24 who were the cohort that gave birth to the most children during the Communist period. This is the result of less social support for childbearing and rearing and increased returns to education causing many women and couples to delay or defer children in favor of increased education and starting careers. Thus, the pattern of fertility across much of the region is beginning to resemble that of Western Europe.

Mortality

At the beginning of the transition period in the early 1990s, the populations living in a large number of Eurasian countries had very poor health outcomes that were inconsistent with their levels of income and development (Feshbach and Friendly, 1992). In Russia, aside from a brief period during the antialcohol campaign in the mid-1980s, the highest life expectancy achieved for Russian men was in 1964 – nearly a half century ago! Russian women only achieved their 1964 peak in 2007. Thus, Russia and a number of other countries in the Eurasian region have completely missed the large declines in mortality and morbidity that has taken place across both developed and developing countries (Lutz et al., 1994). Life style factors – poor diets, high levels of tobacco and alcohol consumption, lack of exercise, and stress – partly account for the gap in Eurasia–Western mortality and morbidity patterns (World Bank, 2005). This pattern of excess mortality applies mainly to the Slavic states of the former Soviet Union (Russia, Ukraine, and Belarus), the three Baltic states, and Kazakhstan, all which all have large Slavic populations. However, the pattern of high mortality affects a large portion of the Eurasian population.

Thus, much of the Eurasian population had poor health outcomes and high mortality even before the disruptive period of extreme social and economic change and initial period of independence of the 1990s when mortality increased and life expectancy declined precipitously across much of the region. The declines in life expectancy are unprecedented for countries not impacted by war or natural disasters. The increases in mortality and declines in life expectancy were universal across the region, albeit to vary levels and with different timing. Life expectancy for Russian men fell by 7.1 years from 1989 to 1994 and by 3.3 years for women in Russia over the same period (**Table 3**). Life expectancy for Russian males has since increased but is still not at the level it was at the beginning of the transition period (Heleniak, 2012). The same is true for the other Slavic states of Ukraine and Belarus. Males in the other Slavic countries of Ukraine and Belarus and the Baltic states had similar but smaller declines. In general, the Slavic states and those countries with large Slavic populations such the Baltics and Kazakhstan had the steepest declines in life expectancy over the period. The countries of Eastern Europe had earlier and smaller declines in life expectancy and faster recoveries, in part attributable to active labor market measures put in place to cushion the restructuring taking place in the labor market (Cornia and Paniccia, 2000). For most of the countries of Eastern Europe, the declines in life expectancy in the early transition period were a temporary blip and life expectancy has since continued an upward trend.

The unique mortality crisis across a large portion of the Eurasian region spawned a large literature examining its causes (Becker and Bloom, 1998; Bobadilla et al., 1997; Eberstadt,

2010; United Nations in Russia, 2008; United Nations Development Programme, 2009). These studies have noted and come to several conclusions. The mortality crisis across much of the region was not due to a collapse of the health care system (there were too many doctors to begin with), worsening environmental conditions (which actually improved as a result of declines in industrial output), or worsening diets. Much of the increase was due to poor coping mechanisms on the part of many in the region as a result of large output declines, periods of high inflation, open unemployment becoming a reality for the first time, large-scale privatization in many states causing rapid labor turnover, the breakup of the three federal states in the region, two with some violence, the large movement of peoples around and within these states, the deterioration of the social safety net – education, health, the social protection system of guaranteed wages and pensions, and the re-writing of the social contract. During periods when mortality increased in the early 1990s, it was those in the middle ages who had the largest increases and the causes of deaths which increased the most were cardiovascular causes and external causes (homicide, suicide, accidents, and drownings) (World Bank, 2009). In Russia, Ukraine, and Belarus, the Baltic states, and to a lesser extent some countries in Eastern Europe such as Poland, Hungary, the Czech Republic, and Slovakia, adult mortality levels are rather inconsistent with infant and child mortality levels, which are relatively low, and inconsistent with their levels of development. In Central Asia and the most of the former Yugoslav states, both child and adult mortality are in line with their income levels.

Another trend that marks a large portion of the population of the region is the large difference between male and female mortality. Globally, women outlive men by 4 years. In more developed countries, the gap is about 7 years and in the less developed about 4 years. In much of the Eurasian region, women outlive men by 8 years and in Russia, Ukraine, and Belarus and three Baltic states, women outlive men by more than 10 years. These are currently the largest female–male life expectancy advantages in the world.

International Migration

International migration has become a major demographic, social, and economic influence on both the people and

countries in the region over the past two decades (Mansoor and Quillin, 2007). Under Communism, migration was tightly controlled by the state and emigration was prohibited except in rare circumstances. There was an attempt to equalize the standard of living across regions and between urban and rural areas, which kept the income disparities between regions rather narrow, thus dampening a major driver of migration.

In the post-Communist period, a number of factors have contributed to greatly increasing the amount and impact of migration. The first has been the liberalization of most of the countries in the region which has included allowing freedom of movement and the right to emigrate. The second has been the increased income disparities among countries in the region and between and countries outside the region. A third factor has been the breakup of three federal states increasing the number of countries in the region from 8 in the late 1980s to 29 currently. Only Poland, Hungary, Romania, Bulgaria, and Albania have remained in their same borders. The breakup of these states added some 45 million persons to the global stock of migrants as defined by the United Nations as somebody residing outside their country of birth.

Each of the Eurasian countries is a nation-state based on one ethnic group. At the time of the breakup of the Soviet Union, 43.4 million persons (17%) of the 15 ethnic groups upon which the successor states are based were residing outside their ethnic homelands (Heleniak, 2013). One of the largest ethnic diasporas to emerge from the breakup of the Soviet Union was the 25.2 million Russians who lived in the non-Russian states of the former Soviet Union. The diaspora population created by the breakup of Yugoslavia in the early 1990s counted approximately 3.4 million ethnic diaspora members, which partially factored into the ethnic conflicts in the region. Thus, a portion of the migration during the 1990s was diaspora migration, people moving to either their place of birth or ethnic homeland.

Migration in the region during the 1990s was marked by large refugee and internally displaced populations, rapid depopulation of regions and countries whose economies were no longer viable under new conditions, migration to outside the region for the first time, large flows of diaspora populations migrating to their ethnic homelands, and new forms of migration in the region such as labor migration. After 2000, the splintering of new states slowed, ethnic conflicts were either resolved or became stalemates, and economic recovery began in all countries in the region. As a result, refugee and IDP (internally displaced persons) flows declined, the return of diaspora populations slowed, labor migration became a fact of life for a number of countries in the region, and many of the countries in the region joined international organizations which measure and regulate international migration flows. A number of Eurasian countries have become members of the European Union and have had large numbers of their citizens migrate to the older EU countries for work.

Income gaps between the Eurasian countries and those of high-income countries in Europe and North American remain wide in spite of recent faster economic growth among the Eurasian countries. During the 2000s, the economy of Russia grew much faster than most of the other CIS countries which largely explains its increased attraction as a migration destination for countries in the region. Differences in levels of economic development within the CIS are significant and widening giving an impetus for migration as predicted by neoclassical theories of migration. Income per capita in Moldova, Uzbekistan, Tajikistan, and the Kyrgyz Republic is less than one-fifth that in Russia. In the first decade of the 2000s, several of these countries have the highest shares of remittances as a share of GDP in the world.

The significance of migration to the countries in the region is reflected in the size of the diaspora populations (based on place of birth) residing outside these countries and the size of the migrant populations within each. Some of these large migrant populations can be attributed to the unique historical circumstances of the emergence of 24 new countries but also the large migration flows which took place in the post-Communist period. Globally, 3.1% of the population reside outside their country of birth. Overall, about 10% of the population originating in a country of Europe and Central Asia reside outside that country (**Table 4**). Albania and Bosnia and Herzegovina have 40% or more of their populations outside their countries, while Armenia, Georgia, Kazakhstan, Macedonia, and Moldova have roughly one-quarter. A number of other countries of Europe and Central Asia have smaller but still significant shares of their populations residing outside their home countries. The Europe and Central Asian country with the smallest percent of its population residing outside the country is the Czech Republic with 4%.

The Eurasian countries are also major receivers of migrants or had large migrant populations when they became independent. In 2010, there were 29 million foreign-born migrants within the Eurasian countries, a decline of 3.3 million since 1990, due to increased restrictions on migration and the increase in various forms of temporary or labor migrant movements which do not include a permanent change in residence.

All of the countries of the former Soviet Union except for Russia had declines in their stocks of migrants. The largest percentage point declines were in Lithuania, Armenia, Latvia, Kyrgyzstan, and Estonia. For the three Baltic states and Kyrgyzstan, the reason was the large decline in the ethnic Russian and Russian-speaking populations. From Armenia, this was due to out-migration of native born ethnic Armenians. Russia's migrant stock increased from 11.5 million in 1990 (7.8% of the population) to 12.3 million in 2010 (8.7%).

Because of the unique historical circumstances of the disillusion of three large federal states, nearly all of the Eurasian countries have larger migrant stocks as a percent of their populations than the global average. There are several groupings of countries in the Eurasian region based on the sizes of migrant stocks. In Kazakhstan, Latvia, Estonia, Ukraine, Moldova, and Belarus, 10% or more of their populations are foreign born because of the large flows of Russians and other Slavic groups to these states during the Soviet period. A similar situation took place in the former Yugoslav states of Croatia, Slovenia, Montenegro, Macedonia, and Serbia. Though 'foreign-born,' many of these

Sources and notes: World Bank, 2013. Global Bilateral Migration Database (http://data.worldbank.org/data-catalog/global-bilateral-migration-database). Data for Serbia and Montenegro are presumably an underestimate because many of the migrants are still counted as being part of a combined Serbia and Montenegro.

people in both the former Soviet Union and former Yugoslavia are long-term residents who are well integrated into their states of current residence. As time goes on, with aging, these migrant stocks in these countries will continue to decrease.

Population Projections and Implications of Trends

The global population is projected to increase by nearly 30% by 2040, to 8.9 billion from 6.9 billion in 2010, with nearly the entire increase taking place in less developed countries. Over the next three decades only the five Central Asian countries of Tajikistan, Kazakhstan, Kyrgyzstan, Turkmenistan, and Uzbekistan, plus Azerbaijan are projected to have population growth (Table 5). All of the others are projected to have population declines. Belarus, Bosnia and Herzegovina, Latvia, Lithuania, Moldova, and Ukraine are projected to have population declines of more than 10% and Bulgaria and Georgia are projected to have declines of more than 20%.

For demographers, the trends in the region of extreme declines in fertility to nearly unprecedented levels, steep increases in mortality, and large-scale emigration from many countries during a period of significant social and economic upheaval provide interesting case studies for re-evaluating some demographic theories. Aside from periods of war or famine, countries of this size have never had such large population declines. Because of the demographic trends of the past two decades, the countries of Eurasia will confront a number of demographic challenges over the coming decades. These include shrinking populations and labor forces because of below replacement-level fertility and older age structures, high mortality in a large portion of the region, aging populations and high dependency ratios, shrinking youth populations and less new entrants to the labor force, and relatively immobile populations (Chawla et al., 2007). Sixteen Eurasia countries are among 20 in the world where the number of deaths exceed the number of births. A large portion of the population in the Eurasia region live in countries where male mortality is far below what is expected given their income and levels of development.

Population Composition by Race and Ethnicity: North America

Jenifer Bratter and Ellen Whitehead, Rice University, Houston, TX, USA

This article is a revision of the previous edition article by A. Morning, volume 17, pp. 11744–11749, © 2001, Elsevier Ltd.

Abstract

This article examines the history and current state of race/ethnic composition within North America, encompassing Canada, the United States, and Mexico. It summarizes general trends in demographic change as well as the complexity of demographic composition by race and major ethnic group. We begin with a brief overview of the historical moments shaping ethnic and racial composition and then provide the most recent estimates of ethnic and racial composition for each region. At the close we provide a comparative analysis, focusing on what the composition bodes for the future.

The racial and ethnic composition of the continent of North America, encompassing Mexico, the United States, and Canada, has undergone a variety of transitions, reflecting in many cases both demographic processes as well as increased complexity of race/ethnic categories. While race and ethnicity are defined differently, their measurement is a common feature of many population registers across the globe (Morning, 2008). The compositions of all nations have become more differentiated, particularly in the United States and increasingly Canada, as 'non-European' subgroups occupy an expanding share of the nation as a whole, translating into a more diverse landscape. On one hand, this reflects the expanding immigrant presence as well as the population momentum driven largely by the children of immigrants and as the growth of interracial unions and multiracial identities (Passel, 2011; Humes et al., 2011; Lee and Boyd, 2007). On the other hand, shifts in composition have also occurred alongside ever-evolving discussion of how best to capture racial and ethnic identity through census classification (Perez and Hirschman, 2009; Goldscheider, 2002), and this increased complexity raises new questions about how race/ethnicity will be captured in the future.

By contrast, Mexican race/ethnic composition has been remarkably stable as the key distinction is linguistic, between Spanish and indigenous speaking peoples, with few official mentions of the small African origin population (de Vidas and Hoffman, 2012). This is not to say that race does not factor into variation within Mexico, as other physical distinctions are a salient part of social variation among Mexican people (i.e., skin color, indigenous appearance). However, capturing race and ethnic variation is less central to the demographic record.

Historical Perspective of North America's Ethnic Composition

We wish to refer readers to the previous article (Tienda and Morning, 2001) for an excellent overview of the historical origins of the peopling of North America. We begin with a brief overview of historical shifts in race/ethnic composition and then explore historical construction of categories that provides the basis of these distinctions. The major categories of race in most records mark the following broad ancestral origins: North American indigenous ancestry, or origins of those immigrating from European, Africa, Asian, or Latin America. The outlying composition of racial and ethnic groups has fluctuated tremendously, fueled by waves of immigration (both forced and voluntary) and differential natural increase. Consistent across all nations within North America is the depopulation of the indigenous populations. The size of the precontact American Indian population has been estimated to range between 1 and 18 million in the United States and Canada (Thornton, 1989) and around 4.5 to 25 million in Mexico (Alba, 1977). Due to deaths caused by infectious illnesses carried by the European settlers, warfare between the Europeans, and genocide, this number is estimated to have dwindled to less than 250 000 as of the 1800s. The total depopulation in America between 1500 and 1890 is estimated to have been around 1.75 to 4.75 million people (Feagin, 2000).

The diminishing indigenous presence corresponded with waves of immigration from Europe, Asia, and Africa. Europeans maintained a large majority in the United States and Canada (between 80 and 90% of the population) (McDaniel, 1995). Some of the earliest nonindigenous presence within the North American territories arrived from Spain and occupied what is now the United States and Mexico, predating that of the English colonists. This presence existed over two centuries, longer than that length of the independent nation of the United States (Rumbaut, 2005: 24–28). In contrast, the early presence of foreigners in Canada primarily consisted of French and English settlers up until the early twentieth century and became more diverse in terms of European origins. Over time, the United States also experienced an influx of English, German, French, Dutch, Irish, and Scotch-Irish. The African presence within North America evolved differently across the various nations with Africans entering as slaves within the United States (known then as the colonies) and Mexico (Feagin, 2000), but entering Canada largely as a free population escaping slavery in the United States and the Caribbean. Between 1600s and 1820s, an estimated 8 million Africans were transported via the Middle Passage, and between 15 and 30% of those kidnapped died aboard ships (Desmond and Emirbayer, 2009). Although the presence of slaves was especially prevalent in the United States, many were transported to Mexico and eventually settled in indigenous villages (Carroll, 2009).

The size and share of the Asian population reflected the impact of restrictive immigration laws and anti-immigrant sentiment that reduced the growth of this group during late 1800s on into the latter part of the twentieth century. The first Asian immigrants to the United States were the Chinese, who arrived between 1840 and 1860 during the California gold rush

and later worked on railways, with the Japanese being the most dominant immigrant group between 1910 and 1950 (Xie and Goyette, 2004). Although small, Chinese immigration to Mexico occurred at the beginning of the twentieth century (Augustine-Adams, 2009). Meanwhile, the major waves of Asian immigrants in Canada began after 1960 when restrictions were largely lifted, inspiring a similarly dramatic increase in the number of non-European immigrants of various backgrounds.

Notably, this demographic growth occurred alongside changes in demographic measurement in ethnic and racial groups. Intermixture between groups, as well as variable notions of how and on what basis to define racial groups, created ambiguity in how these categories could be applied. The category 'White,' for example, did not initially include members of Italian, Spanish, or Irish descent as it did for persons of French or English descent (Perez and Hirschman, 2009). While membership within the African-American or Black category has been defined under the 'one-drop rule' (i.e., returning anyone of any African admixture to this category), categories of partial African descent (e.g., mulatto, quadroon, octoroon) were classified during the 1800s and early 1900s. The number of Asian ethnic groups on the census expanded from one census to another, reflecting increasing concerns over immigration from this region. Persons of Mexican origin, who may be considered Latino today, were classified as 'White' as a condition of the annexation of Mexico into Texas. Only in 1930 would there be a 'Mexican' on the census, which was removed in the following year. Changes and measurement of race/ethnic composition have historically evolved.

Contemporary Trends of Ethnic and Racial Population Composition in North America

As we move through the second decade of the new millennium, we can see that patterns of ethnic and racial change have taken a variety of forms, mostly that maintain the trajectory established in the beginning of the decade. On one hand, we observe a diminishing share of populations that occupy the race/ethnic majority while 'non-White' immigrant groups expand. On the other hand, classification schemes have also become even more complex, with options to express multiple origins and more detail and specificity provided to particular ethnic and racial categories. Taken together, these patterns point to two salient issues in social demographic study of race/ethnic composition: (1) the ever-expanding diversity and (2) the complexity of race/ethnic measurement.

Canada

Canada's multicultural landscape, like the United States, has been characterized by immigration that has spurned growth among non-European ethnics, altering the balance between these groups and the European majority. Following the removal of ethnic restrictions that limited immigration from non-European countries, immigration from these countries increased, particularly from Asian. Characterizing this changing composition in the demographic record has tended to emphasize ethnic distinctions as opposed to 'race.' Table 1 shows the distribution of the population across ethnic origin designations, according to the quinquennial Census, from 1996 to 2011. Although the government conducted an 'Ethnic Diversity Survey' in 2002, conclusions are difficult to draw from a one-time study, and data from the past 10 years would be missing, as well. What is immediately apparent is the shift in usage and level of detail of particular categories of ethnic groups between 1996 and 2001 (with empty cells noted with N/A). This is an oft noted feature of Canadian census composition (see Goldscheider, 2002 for discussion), limiting the appraisal of changing composition over time.

Some shifts occur on what aspects of ethnicity are recorded, with the use and then removal of parental ethnicity (specifically from male ancestors) or the inclusion of racial designations via the 'visible minority' classifications (see Table 2). Others reflect changes in usage, naming, and degree of detail. For example, as of 1996, residents can declare their origins as 'Canadian' or the

formerly distinct category of *Arab* has been absorbed into a broader category of *West Central Asian and Middle Eastern Origins* in the most recent census. Some groups shift their place in broader categorization, such as *British Isles* and *French* origins being included among the broader category of 'European' in the most recent census. Even ethnic origin groups that have always been present on the census rolls, specifically African and Aboriginal, have changed their naming over time or have been tracked with greater detail within the category. This ever-changing nature of the Canadian census reveals that political nature of census classification, impacted by needs of policy makers and the public.

Over the past 15 years, the population of Canada has become more ethnically and racially diverse, marked by an increasing shift in demographic balance favoring non-European origin groups and visible minorities. The population has grown overall, from 28 million in 1996 to 32 million in 2011, an increase of about 15%. The majority of Canada's population is single origin, though increasingly Canadians are reporting multiple ethnic origins; the single-origin share has diminished from roughly two-thirds (64%) to a little more than half (57%) in 2011. This change is driven by the decreasing share of the population that identifies as European, from 34% in 1996 to 22% in 2011, and Canadian, from 23% in 2001 to 18% in 2011. Absolute numbers of these groups have also dropped with the British Isles population, declining from 3.3 to 2.5 million, and the drop in the French origin population from 2.7 to 1.2 million. Meanwhile, all other non-European origin groups have expanded their shares, with the percent of Latin, Central, and South American; African, and South Asian origin more than doubling in this time span. The Asian population, the fastest growing and largest non-European ethnic group, has doubled in numbers from around 2 million in 1996 to over 4 million in 2011 and its share from 6% in 1996 to 12% in 2011. Overall, the expanding groups are those hailing from most recent waves of immigration that is non-European, drawing greater attention to distinguishing racial and as well an ethnic variation.

We now turn to variation in visible minority status, shown in Table 2. These figures show the impact of continual immigration from non-European nations, as well as the population momentum created by their presence. Visible minorities refer to "persons, other than Aboriginals, who are non-Caucasian in race or non-white in skin color" (Hamplova and Le Bourdais, 2010: 1538). A minority but growing share and size of the population identifies with one or more of the visible minority categories, growing from 11%, or 3.1 million persons, to 19%, or 6.2 million persons, during this period. Each visible minority population, such as the numerous Asian categories, Blacks, Filipinos, and Latin Americans, have made small but steady increases during this time period, both proportionately and in absolute numbers. Unlike the United States, the largest racial minority groups are ethnically Asian. South Asians and Chinese are the largest groups, encompassing roughly 6–8% of the population (derived from summing these two groups). Blacks are the next largest group, growing from 2% to nearly 3% in 2011, followed by Filipinos, Latin Americans, and Arabs, whose share is a little more than 1% of the population as of 2011. Among the remaining groups, South Asians, Koreans, and those declaring multiple categories have more than doubled their numbers.

United States

Similar to Canada, the United States is increasingly diverse. However, unlike Canada, this process has been faster, with population projections predicting ethnic/racial plurality with no clear majority in the next 30 years. The change is already apparent in births, as one-fourth of nation's children as of 2010 can be considered 'immigrant youth;' that is, they are either foreign-born or are children of first-generation parents (Passel, 2011). Children are the most diverse age group, as the United States witnessed its first birth cohort with no racial majority as non-Hispanic Whites encompassed (slightly) less than half of babies born. This increasingly diverse composition has a spatial component as well, with four states the District of Columbia, and one-tenth of all counties have 'majority–minority' populations (Humes et al., 2011).

In Table 3, we show the composition of the US population by race and Hispanic ethnicity from 1990 to 2010. The categories set forth by the Office of Management and Budget, the federal agency charged with setting the standards for race/ethnic classification, place Hispanics, regardless of race, in a separate category and provide race categories for non-Hispanics. We provide more detail here, showing the race of Hispanics and non-Hispanics. In addition, as respondents are now (since 2000) allowed to declare multiple race responses, the major categories specify those persons who marked this category 'alone.' We also place all persons selecting more than one race in a separate category as well, among Hispanics and non-Hispanics. The US population continues to grow, adding 60 million people between 1990 and 2010. The majority of population 'non-Latino,' though Latinos are among the fastest growing group, increasing their share from 9 to 16% from 1990 to 2010. Latinos are now the second largest ethnic/racial group,

n/a: Category not available at the corresponding Census year.
[a]The category 'Asian alone' was the category 'Asian or Pacific Islander' in the 1990 Census.
[b]The category 'American Indian and Alaska Native alone' was the category of 'American Indian, Eskimo, or Aleut' in the 1990 Census.

replacing African-Americans, who had been the largest 'non-White' group since the first Census that was taken in 1790. This group represents a stable 12% of the population. Asians are also quickly expanding their numbers, from less than 3% to nearly 5% in 2010. In addition to immigration and population momentum, the composition of the United States has also been affected by increasing interracial unionship, evidenced by the growing number of persons claiming two or more races are also growing, from 1.6 to 1.8%.

We now turn to more detailed examination of ethnicity in **Table 4**, providing ethnic information for Hispanic and Asian populations. The majority of the Hispanic population (see panel A), nearly three-fourth, is ethnically Mexican, followed by Puerto Ricans and Cubans, together who make up less than 20%. A sizable share of this group also hails from Central and South America. This ethnic mix include a wide range of perspectives on issues of racial and ethnic identity and as such, some argue that ethnicity for Hispanics provides more specific information on origins than race, given that nearly half identify racially as 'Some other race' (Perez and Hirschman, 2009). Turning to Asians (in panel B), this racial category masks a wide range of ethnic diversity, as no one group represents more than 21%. Chinese are the largest ethnic group, followed by Asian Indians, Filipinos, and Vietnamese. This also reflects the impact of recent immigration, as Japanese and Koreans were more prevalent shares of previous flows of Asian immigrants (Xie and Goyette, 2004). The variation in immigration histories of these 'new' groups provides important complexity to the pathways of Asian incorporation.

Mexico

Unlike Canada or the United States, the key ethnic or racial distinctions in the official record of Mexico is linguistic, specifically whether a person speaks Spanish or an indigenous language. As a nation which is known for emigrants and low immigration, this division in language emphasizes the groups that already reside in Mexico, unlike the United States and Canada, for whom tracking immigrants has been salient in their record keeping. By contrast, the Mexican census gives little focus to newcomers to the country that may vary linguistically. This system of classification based on spoken languages allows an assumed distinction between those groups which have existed in Mexico for centuries or more: the indigenous Mexican population and those of whole or partial European origin. Exclusion of a *racial category* from the Mexican census is based upon the supposition that almost every national of this country is 'mestizo' (Spanish for mixed race), as well as the government's perception that Mexican society had become increasingly panracial and integrated (Augustine-Adams, 2009). As shown in **Table 5**, the number of Spanish speakers and indigenous language speakers have both increased over the past decade and a half, but the population who speaks only Spanish has increased at a slightly faster rate (a linear increase of 25.4 compared to 22.1). Those who solely speak Spanish still constitute the vast majority of the population, comprising 93% of Mexicans compared to 7% who are indigenous speakers.

Looking at their proportion to Spanish speakers in the population, most indigenous language speakers were concentrated in the southern states of Mexico in 1995, and this trend continues up through 2010. Over one million indigenous speakers resided in both Oaxaca and Chiapas in 2010, and Veracruz, Querétaro, and Yucatán all had over half a million indigenous speakers this same year. All but one state (Yucatán) increased in absolute numbers of their population of indigenous speakers, yet half decreased in terms of the proportion of the total state population these speakers constituted. These numbers indicate a gradual trend toward a nation with a smaller indigenous population – or at least, a nation with a small number of

people who speak these languages. These numbers do not reflect the small but significant African origin or Black population in Mexico (Augustine-Adams, 2009).

Comparative North American Perspective: Looking toward the Future

The future of race/ethnic composition in the North American region is likely to be one of increased complexity. According to US Census projections, the United States will become the first nation in the region to have no ethnic/racial majority. Meanwhile, Mexico, as in other Latin American countries, is beginning to undergo a shift in classification to allow for more detail to recognize Indigenous and Black communities (de Vidas and Hoffman, 2012). In Canada, populations of multiple ethnic origins expand tremendously, but visible minority remains small. This raises the question whether classifications approaches will remain stable or, might there be another change on the horizon as the population becomes more ethnically fluid.

In addition, interracial family formation has become more common yielding both more mixed-race families and more multiracial offspring. Both nations have official mechanisms in place to capture multiple origins to track the growth of multiple-ancestry population and to enable incorporating such groups into official statistics. Importantly, expansion among the 'multiple origin' or the two or more race populations may undo notions of rigid race/ethnic categorization around single-origin groups. However, single-origin groupings have tremendous political significance, and therefore it is also highly possible that classification will accommodate for increased blurring without fundamentally shifting how populations are organized.

Abstract

A population cycle is a roughly periodic variation over time in the size or composition of a population. Here, composition refers to the component structure of the population, for example into distinct age classes. The formal theory of population cycles consists of mathematical tools that yield qualitative and quantitative information about the characteristics of cycles, such as their amplitude or period. There are three broad types of cycle: *transient cycles* are a response to a perturbation of finite duration such as a fertility transition; *externally driven cycles* are triggered and sustained by a persistent external perturbation such as an economic cycle; *internally driven cycles* are maintained by interactions within the population such as a feedback between cohort size and cohort fertility. This article discusses the theory for these three types of cycles, dealing mainly with age-structured populations, although other aspects of population structure are mentioned.

A population cycle is a roughly periodic variation over time in the size or composition of a population. Here, composition refers to the component structure of the population, for example into distinct age classes. The formal theory of population cycles consists of mathematical tools that yield qualitative and quantitative information about the characteristics of cycles, such as their amplitude or period. There are three broad types of cycle: *transient* cycles are a response to a perturbation of finite duration such as a fertility transition, *externally driven* cycles are triggered and sustained by a persistent external perturbation such as an economic cycle; *internally driven* cycles are maintained by interactions within the population such as a feedback between cohort size and cohort fertility. This article discusses the theory for these three types of cycles, dealing mainly with age-structured populations, although other aspects of population structure are considered briefly.

Mechanisms Driving Population Cycles

To explain the different mechanisms that drive cycles, and the kinds of formal theory that are required, it is useful to begin with Lotka's classical demographic equation which relates births $B(\mathrm{t})$ at the present time $t > 0$ to past births, by summing the reproductive contributions $\phi(a, t)$ made by individuals of all ages a, as

$$B(t) = \int_0^t \mathrm{d}a\phi(a,t)B(t-a) + H(t). \qquad [1]$$

Here $H(t)$ specifies births to individuals who were present at $t = 0$, and immigration is ignored. The theory of this classical demographic model is discussed in Population Dynamics: Theory of Stable Populations; Population Dynamics: Classical Applications of Stable Population Theory; Population Dynamics: Theory of Nonstable Populations.

Transient cycles typically occur in a population whose vital rates, i.e., mortality and fertility, change over a time interval, say from $t = 0$ to $t = t_1$, and are constant thereafter. A practical example of such a perturbation is a decline from high fertility to replacement fertility that starts at $t = 0$ and is completed at $t = \mathrm{t}_1$. After time t_1, the population is described by classical demographic theory and undergoes damped oscillations towards the classical stationary state. But the dynamics during the transition are also oscillatory and require a different treatment.

Externally driven cycles result from a persistent perturbation of vital rates. One example is a periodic variation over time in fertility that is generated by an exogenous force, such as an economic cycle in wages. Another example is an irregular, stochastic variation in fertility or mortality that produces an ongoing stochastic response that has cyclical components. Formally, such perturbations are described by an appropriate time-dependence in the function $\phi(a, t)$.

Internally driven cycles result from changes in vital rates that are driven by changes in population size and composition. In such cases, the net reproduction $\phi(a, t)$ has a functional dependence on the past trajectory of births, or on past vital rates. One example is a relationship between the fertility of a cohort in its childbearing years with the size of the cohort: for a substantive discussion of such relationships, *see* Fertility Transition: Economic Explanations. Another example is provided by inverse projection in historical demography (Lee 1977), in which observed counts of births and deaths over time are used in conjunction with the Lotka equation to estimate the time-variation in the level of mortality rates. Here, the constraint of matching observed counts results in a feedback between the level of mortality and population counts (Wachter 1986).

The formal theory of cycles driven by each of these mechanisms is discussed below, followed by a brief consideration of future directions.

Transient Cycles

A perturbation such as a fertility transition may take decades to complete, and a formal theory must provide formulas for the birth sequence $B(t)$ both during and after the perturbation. Li and Tuljapurkar (1999b) provide an explicit if cumbersome

description of the decaying population cycles that result from a perturbation. This theory shows that the population undergoes damped cyclical changes during and after the transition. The characteristics of these cycles have not been explored except in particular cases; but this analysis makes possible the computation of population momentum for all gradual transitions (Li and Tuljapurkar 1999a). It is worth noting that the analytical results for this case rest on properties of the roots of Lotka's equation. The relationship between these roots and the age-pattern of reproduction has been studied by approximate (Keyfitz 1985) and exact (Wachter 1984) methods that are also useful in the analysis of externally and internally driven cycles.

Externally Driven Cycles

An illuminating treatment of population cycles driven by external periodic variation in reproduction was given by Coale (1972), who showed that the population responds with periodic variation in the numbers and relative sizes of its age components. The challenge for the theory lies in the nonlinearity of eqn. (1) when $\phi(a,t)$ contains a periodic component. To see this, suppose that $\phi(a,t) = \phi(a) + \psi(a,t)$ with ψ being periodic in time t, and suppose that the resulting birth sequence in eqn. (1) has the form $B(t) = B + b(t)$, with b also a periodic function. Substitution of these forms into eqn. (1) shows that the unknown b(t) depends on a nonlinear product $\psi(a, t-a)\ b(t-a)$. General results for nonlinear renewal eqns. of this type are not known. There are analytical approximations which employ an expansion in the amplitude of the periodic perturbation ψ; these describe the amplitude response of the population and the phase difference between population cycles and the external driving cycle (Tuljapurkar 1985). An interesting class of periodically perturbed Lotka models has been described and analyzed exactly by Kim and Schoen (1997), Schoen and Kim (1994, 1997). The latter work demonstrates that it is sometimes possible to solve exactly the homogeneous form of equation (1), i.e., with $H = 0$, for an explicitly time-dependent $\phi(a, t)$. Such analytical examples can be valuable as a source of insight into the dynamics, and as a check on approximate theories intended for less tractable problems.

The analysis of periodic perturbations suggests that a persistent stochastic perturbation of vital rates will also generate a superposition of cycles of population change. The dynamics of a population subject to stochastic perturbation are also nonlinear, so again the theory has relied upon approximations. Lee (1975) pioneered the application of time-series methods to the linearized analysis of stochastic perturbations. To go beyond linearization, e.g., if the perturbations are large or have strong positive serial correlations, a higher order approximation may be used as discussed by Tuljapurkar (1990), Tuljapurkar and Lee (1997).

Internally Driven Cycles

The formal analysis of internally driven cycles is quite distinct from the analyses used in classical demography, and draws on developments in nonlinear dynamics (for a review of modern nonlinear techniques for dynamics, see Guckenheimer and Holmes (1983)). To start with, it is important to recognize that there are different forms of internal feedback. One class of feedback is exemplified by cohort size effects on fertility: large birth cohorts go on to have lower fertility than their parents and the opposite for small birth cohorts (Lee 1974, 1976, Wachter and Lee 1989). A second class of feedback is generated by social norms or expectations: for example, individual fertility is influenced by the average fertility in the population (Kohler 2000). A third class of feedback arises through an interaction between a population and external variables – for example, economic conditions, environmental conditions, or resources such as land holdings – and these external variables in turn influence fertility or mortality (Bonneuil 1990, 1992, 1997, Chu 1998, 1999, Feichtinger and Sorger 1990, Feichtinger and Dockner 1990, Lee 1987, Milik and Prskawetz 1996).

The formal theory of such feedbacks shares several elements that may be illustrated by considering a nonlinear version of Eqn. (1). Suppose that the net reproduction $\phi(a,t)$ in that equation changes with the population structure: for example, the fertility of individuals aged a at time t depends on the size of that cohort relative to the size of their parents' cohort. Such feedbacks result in a functional relationship of the form

$$\phi(a,t) = \phi(a)h(g,a,\{B(t-s), 0 < s < S\}). \qquad [2]$$

Here the function h on the right describes the effect of the other birth cohorts, born as long as $S > 0$ years ago, on the fertility of the cohort aged a. The parameter g controls the strength of the feedback, for example, by controlling the gradient of h. Lotka's equation is now a nonlinear renewal equation, which can be written in abstract form as

$$B = \mathscr{L}(\mu, B). \qquad [3]$$

The nonlinear operator $\mathscr{L}$ maps past values of births into their current value. This verbal description can be formalized suitably; for an example of the mathematical details see, e.g., Cushing (1978).

In most applications the nonlinear eqn. (3) has a constant solution, $E(\mu)$. The dynamic stability of this solution is examined by studying small deviations $x(t) = \{B(t)-E(n)\}$: stability means that $x(t)$ should decrease over time. An expansion of the nonlinearity in eqn. (3) yields a series of terms of the form

$$x = \mathscr{H}(\mu,x) + \mathscr{G}(\mu,x,x) + \mathscr{R}. \qquad [4]$$

The operator $\mathscr{H}$ is a linear operator, $\mathscr{G}$ is quadratically nonlinear, and $\mathscr{R}$ involves higher-order nonlinear terms. Local stability is determined by the eigenvalues of the linear operator $\mathscr{H}$, and these in turn depend on the elasticity of the linear response (Wachter 1991a). In typical examples, the equilibrium is locally stable when $g < g^*$, say, but becomes unstable when $g \geq g^*$. Local instability means that small deviations from the equilibrium births will change with time as $\exp\{(p + iq)t\}$ where $p > 0$ and q are given by eigenvalues of the linear operator $\mathscr{H}$. The local change in $x(t)$ follows a cycle of period $(2\pi/q)$. The central question now is: when such local instabilities grow and experience the nonlinear forces in equation (4), will they turn into sustained, stable cycles? If they

do, increases in the parameter g past the threshold value g^* will generate a sustained population cycle, called a *limit cycle*. Since $E(\mu)$ is still a constant solution, eqn. (3) (or its solution) is said to have undergone a bifurcation at $g = g^*$.

For any value of g above but not far from the threshold g^*, the nonlinear limit cycle may be represented by a superposition of periodic solutions to the linear part of eqn. (3). Numerical illustrations of such limit cycles are given by Frauenthal and Swick (1983). A systematic procedure for computing the amplitude, period, and stability properties of this limit cycle beyond the bifurcation point is described by Tuljapurkar (1987), and substantive applications that illustrate these computations are given by Wachter (1991b) and Chu (1998). These procedures may be extended to many other models with feedback, and provide an important part of the theory of population cycles. Other feedback mechanisms may result in a different approach to bifurcation (e.g., bifurcation in fertility level, Kohler 2000).

New Directions

The formal theory of cycles has moved considerably beyond classical demographic theory. The nonlinear bifurcation analysis discussed above can be considerably extended. Wachter (1994) has explored global properties of feedback models, addressing the behavior of cycles far above a bifurcation threshold. Bonneuil (1992), Prskawetz and Feichtinger (1995), and Tuljapurkar et al. (1994) show that increasing feedback can lead to more complex types of population cycles including aperiodicity and chaos. Purely internal feedbacks may not be strong enough to generate demographic cycles in human populations, but feedbacks mediated by social or external interactions may well be strong enough. The challenges that face the theory now lie in two areas: confrontation with data to test and modify theories, and the development of new models that incorporate a wider range of demographic dynamics and interaction. As yet, nonlinear cycles in human populations have not been examined in the realistic and rich way that biologists have explored cycles in the structure of laboratory populations (de Roos 1997, Cushing 1997).

Abstract

If age-specific fertility and mortality rates are constant for a long period of time, a population will approach a fixed age distribution, and fixed overall rates, which can be calculated from the specific rates. An assumption of stability may thus enable the indirect estimation of missing data when only a few population characteristics are known. Even when the assumption is not satisfied, the stable population model provides a useful approximation to the relationships among survivorship, reproduction, and age structure. Several applications are provided, ranging from the simple exponential model of population growth to models that estimate numbers of kin.

Introduction

The theory of stable populations is presented in both continuous and discrete form in the article Population Dynamics: Theory of Stable Populations. Virtually any real population, whether contemporary or historical, deviates from stability, but the stable model produces a standard for comparison based on simplifying assumptions that allow us to handle data limitations. Some applications of the theory appear in the introductory article just mentioned and in other articles, including Demographic Techniques: Indirect Estimation; Population Dynamics: Momentum of Population Growth. The present article will review several applications within a structure that specifies the amount of information that is required. The applications are 'classical' in the sense that they are relatively well known.

It is helpful first to distinguish between two classes of models that are widely used: survival processes and renewal processes. The prototypical example of a survival process is the single-sex, single-decrement life table, described in the article Life Table. A survival process describes a cohort, real or synthetic, from age 0 until some terminal age ω. The main concepts are (a) the survival function, $l(x)$, namely the proportion of the cohort that survives to each age x, and (b) the mean waiting time or remaining life expectancy, e_x^o, at any specific age x.

A renewal process, by contrast, is a survival process with reproduction. With this component, the process generates successive cohorts that are (in general) larger than necessary simply to replace the persons who have died. The cohort interpretation is supplemented with the asymptotic implications of fixed and stable overall rates (of growth, mortality, and fertility), and a fixed and stable age distribution, none of which depends on initial conditions.

If a renewal process is in equilibrium – that is, if reproduction is exactly at replacement value, then the stable population is stationary. It has an intrinsic growth rate of zero, and one does not need explicit age-specific birth rates to analyze it, for its overall birth rate is identical to the overall death rate. There are several classical applications and generalizations of this scenario, all of which can be regarded as applications of stable population theory because a survival process is a special stable renewal process.

A stable population is typically motivated as the asymptotic consequence of projecting the population indefinitely with fixed age-specific rates. Its overall rates and age distribution converge to functions that do not depend on the initial conditions. However, unless the intrinsic growth rate is zero, there is a fundamental implausibility in this asymptotic interpretation. If the intrinsic growth rate is positive, then the overall population size will increase exponentially, an outcome that cannot be sustained indefinitely in a real population. If the intrinsic growth rate is negative, then the overall population size will *decrease* exponentially until eventual extinction. In probabilistic terms, the fixed-rates assumption implies almost certain ultimate extinction or explosion (*see* Population Dynamics: Probabilistic Extinction, Stability, and Explosion Theorems). It is probably more useful to regard the stable population parameters simply as a synthesis of the underlying age-specific probabilities or rates.

Applications Not Requiring Schedules of Rates

Applications of stable population assumptions can be organized according to the amount of information they utilize. Probably the simplest possible applications occur when the only parameter utilized is the intrinsic growth rate, r. If we assume stability between two times t_1 and t_2, and that the population size at those two times is n_1 and n_2, then

$$n_2/n_1 = e^{r(t_2-t_1)}$$

Solving for r, we get

$$r = (\ln n_2 - \ln n_1)/(t_2 - t_1)$$

We can then estimate the population size at an intermediate time, $t_1 \le t \le t_2$, to be $n_t = n_1 e^{r(t-t_1)}$. This formula, or variations upon it, is often used when the population is not stable, in the absence of better information. Another simple and well-known application is to determine the doubling time associated with a given value of r. Setting $n_2 = 2n_1$ and letting T be the time required for the population to double, we obtain $2n_1 = n_1 e^{rT}$, leading to $T = (\ln 2)/r = 0.6931/r$. For example, if the annual growth rate is 0.01, or 1 percent, a stable

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31134-5

population will double in 69.31 years, or approximately seventy years. These and related applications are discussed by Hinde (1998: pp. 154–8), for example.

Suppose that in addition to the intrinsic growth rate, r, we also know the intrinsic birth rate, b (and hence the intrinsic death rate $d = b - r$). Keyfitz (1977: pp. 12–14) uses such information to estimate the number of persons who have ever lived on Earth, which is the same as the number of persons ever born. His strategy is to piece together long intervals of time within which stability (at different levels) is assumed. If the population is stable between t_1 and t_2, then the number of person-years lived in that time interval will be

$$PY = \int_{t_1}^{t_2} n_1 e^{r(t-t_1)} dt = (n_2 - n_1)/r$$

PY can be converted to the corresponding number of births by multiplying by b:

$$B = bPY = b(n_2 - n_1)/r$$

(If $r = 0$, then $n_1 = n_2 = n$, $PY = n(t_2 - t_1)$, and $B = bn(t_2 - t_1)$.)

Applications that Assume Schedules of Rates

Another class of applications arises if we know r, b, and d, and do not know the survival and fertility schedules but are willing to make some assumptions about them. Coale and Demeny (1983) blended empirical life tables into four sets of so-called regional model life tables (north, south, east, and west) for males and females, keyed to the life expectancy e_0^o at birth and e_{10}^o at age 10 (*see* Demographic Models). They also developed plausible fertility schedules, varying according to the mean age of childbearing but adding up to one child, so that the entire schedule could be multiplied by a hypothetical total fertility rate (TFR). With this information, much of it hypothetical, they were able to generate sets of stable age distributions. It is then possible to estimate a wide range of population characteristics, using only a few pieces of summary information (along with a specification of region and sex). The summary information typically includes certain combinations of the following: a measure of growth, such as r; a measure of fertility, such as b, the gross reproduction rate (GRR), or the TFR; a measure of mortality, such as d or the average age at death; or a measure of the age distribution, such as the proportion of persons below age 20. Stable age distributions generated in this way can also be used to approximate real age distributions in settings of deficient data. Some methods for the computation of population parameters using the stable population model are described in Demographic Techniques: Indirect Estimation.

Applications that Require Schedules of Rates

A number of analyses of population dynamics have resulted from examining the sensitivity of population characteristics to disturbances of a stable population. These applications require knowledge of the age-specific schedules for mortality (say m_x for each age x), of fertility (say f_x for each x), and for any other transitions in the model. For example, Preston (1974) took partial derivatives of the basic stable population formulas to estimate the effect of various age-specific mortality changes upon the intrinsic growth rate, birth rate, and age composition. He found that the effects could be represented as simple functions of the age pattern of the cumulative changes in the mortality rates. Probably the best known of these sensitivity analyses has been on the topic of population momentum, which in its simplest form measures the eventual effect on population growth of an immediate shift to replacement fertility (*see* Population Dynamics: Momentum of Population Growth).

The classical stable population model has no in- or out-migration, but several authors have used the model in innovative ways to evaluate the impact of emigration (Keyfitz, 1971) or immigration (Lesthaeghe, et al., 1988). Mitra (1990) considered how a population could maintain stationarity through a combination of below-replacement fertility and a steady stream of immigration. With assumptions about the ages and fertility of the immigrants, it is possible to determine the necessary size of the stream of immigration. This model is relevant, at least as a first approximation, to the current mix of below-replacement fertility and immigration in Europe and North America.

The classical formulation of stable population theory only allows individuals to be born, procreate, and die, but later developments permit individuals to move between several statuses or states during their lifetime, as in multistate models (*see* Multistate Transition Models in Demography). In one obvious application the states represent regions of a territory (Feeney, 1970). In another, Keyfitz developed a linkage between aging and career mobility in stable populations (1973; the title of this paper is misleading because he included stable as well as stationary populations). He supposed that advancement in status across a set of discrete categories is essentially based on the steepness of the age distribution. In a setting of high growth, age (as a proxy for experience) tends to produce earlier advancement because there are relatively few people at higher levels. In a setting of low growth, seniority is less valued, because there are relatively many people at higher levels, and promotion will take longer. The approach is again a type of sensitivity analysis, in which the age at reaching a sequence of discrete gateways is expressed as a function of stable population parameters (in particular, the intrinsic growth rate).

Applications that Link Individuals to One Another: Kinship

Assume now that we have access to complete schedules of survival and fertility. In continuous form, say that $l(x)$ is the probability that a woman will survive to age x and $m(x)\,dx$ is the probability that a woman will have a daughter between ages x and $x + dx$ (with $m(x) > 0$ for x in the reproductive age range $\alpha < x < \beta$ within the full range of ages $0 < x < \omega$).

Single-sex kinship provides a structure by which individuals are linked through lines of descent or ancestry. Two specific models for kinship structures will be described here. In the context of kinship, reference individuals (ego) are linked to their direct descendants, such as daughters; to progenitors, such as mothers; or to their lateral kin, such as sisters. Two-sex approximations are possible. The main outputs are the

probability that a specific progenitor is still alive when ego is age a, and the expected number of descendants and lateral kin (in a specific category) who are still alive, or were ever born, when ego is age a. These are obtained from various convolutions of the survival and fertility functions.

The first kinship model to be described was developed by Goodman et al. (1974, 1975). The following exposition will be limited to surviving kin when ego is age a. It can be modified to refer to kin ever born simply by deletion of the outermost survival function (that is, setting it equal to 1).

Each kinship role is expressed with a different formula, but the strategy for generating these formulas is the same for all roles. The steps to link ego with a consanguineal relative are to identify the relevant sequence of births, and the ages of the respective mothers at those dates; to incorporate the fertility rates for those ages, the probability of surviving to those ages, and, for the final link, the probability of surviving to the time when ego is age a; and integrating over all allowable combinations of ages of the linked kin. Note that the birth of ego herself, and her survival to age a, are assumed.

For example, to link ego with her daughter, the relevant birth is that of the daughter, which occurred when ego was some previous age x. If the daughter is still alive when ego is age a, then the daughter's age is $a - x$. Thus ego experienced the fertility rate for age x, and the daughter survived to age $a - x$. Multiplying in reverse order and integrating over allowable ages x, the expected number of surviving daughters for a woman age a is

$$D(a) = \int_{\alpha}^{a} l(a-x)m(x)\mathrm{d}x$$

(If $a < \alpha$ then $D(a) = 0$ and if $a > \beta$ then $D(a) = D(\beta)$.)

The stable population probability that ego's mother is alive when ego is age a was originally calculated by Lotka (1931), and is useful for estimating adult mortality when some empirical information about the incidence of orphanhood is available. If the mother was age x when ego was born, then the probability that she is still alive a years later is the probability of surviving to age $a + x$, $l(a + x)/l(x)$. Obviously this depends on the value of x, as well as a, and these survival ratios must be weighted by the probability that the mother was age x to age $x + \mathrm{d}x$ when ego was born. In a stable population these weights will be given by $W(x)\mathrm{d}x = \mathrm{e}^{-rx}l(x)m(x)\mathrm{d}x$ (from the characteristic equation, this is the density function for mothers' ages and integrates to 1). Therefore,

$$M_1(a) = \int_{\alpha}^{\beta} [l(a+x)/l(x)]W(x)\mathrm{d}x = \int_{\alpha}^{\beta} e^{-rx}l(a+x)m(x)\mathrm{d}x$$

is the probability that ego's mother is alive when ego is age a.

The expected number of surviving sisters when ego is age a involves a similar logic but will not be given here. Ego is linked to her sisters through their mother. It is necessary to distinguish between older and younger sisters because the survivorship of the mother is problematic after, although not before, the birth of ego. The formulas can be extended to aunts, nieces, first cousins (mother's sister's daughters), and indeed any category of kin.

A noteworthy feature of this application of the basic model of a stable population is that it requires only the basic survival function and maternity function, and a structure to link individuals. As an alternative to linkage by kinship, it should be possible to substitute an organizational structure or some form of vertical and horizontal connections, but we are not aware of any analogous applications.

The formulas are deterministic, rather than stochastic, and will not produce distributions. They assume that the birth of a child is independent of the number of children a woman has already had, that survivorship is independent of biological relationship, and that the population is homogeneous. Although these limitations are severe, it would be difficult to find data corresponding to more realistic assumptions. Calculations using these multiple integrals require some form of quadrature.

In a second application of kinship (Pullum, 1982), counts are not conditional upon the survival of ego or any other kin, but are defined as 'eventual expected' numbers of kin. For example, the net reproduction rate

$$N = \int_{\alpha}^{\beta} l(x)m(x)\mathrm{d}x$$

is the average number of female births that will be produced, a generation later, from a single female birth. This is equivalent to the eventual expected number of daughters that a woman (ego) will have, defined at the point of ego's birth and the daughters' births.

The eventual expected number of sisters, defined at the point of ego's births and the daughters' births, can be referred to with the symbol S. N is not equivalent to any of the functions defined by Goodman et al. (1974) but S does appear within their scheme as the (expected) number of sisters (older and younger added together) ever born by the time ego has reached age $\beta - \alpha$, the maximum age at which a sister can be born. This formula superfluously conditions on the survival of ego, but allows for all sisters to be born.

It can be shown that N and S are sufficient to obtain the eventual expected numbers of any other types of kin. For example, an average of N^2 granddaughters (daughters of daughters) will be born, SN first cousins (daughters of sisters of the mother), SN nieces (daughters of sisters), and so on. The sex ratio at birth will also be constant in a stable population, and by including it one can easily extend to a two-sex kinship structure. For example, define s to be the ratio of males to females at birth, so that for every female birth there will be $1 + s$ births of males *and* females. This implies that for every female child there will be $1 + s$ children, so N is replaced by $(1 + s)N$; for every sister there will be $1 + s$ siblings, so S is replaced by $(1 + s)S$. (Note that instead of one mother there will be exactly two parents.) The number of grandchildren (sons and daughters of sons and daughters) will be $(1 + s)^2N^2$; the number of first cousins (sons and daughters of brothers and sisters of the mother or father) will be $2(1 + s)^2SN$; the number of nieces/nephews (sons and daughters of brothers and sisters) will be $(1 + s)^2SN$; and so on.

Like the applications given in Section Applications that Assume Schedules of Rates above, this second model of kinship only requires summary measures of the stable population (in this case S and N), and does not require any schedules of rates.

Conclusion

These applications have been presented largely at a conceptual level, without the specific data or numerical conclusions that might help to demonstrate their value (the bibliography and other entries in this encyclopedia describe several further examples). In each case, however, the original goal was to utilize stable population theory to draw approximate conclusions about real populations in situations where data are scarce. The model approximation has certain elegant formal properties and in effect permits the simulation of data that are generally not available for real populations. Indeed, significant improvement in the availability of demographic data is a likely reason why there have been relatively few new applications of the theory in recent decades.

Abstract

Whereas interactions of population and natural resource growth have generally been modeled using large-scale numerical simulation studies, we review small-scale models that permit partially analytical results and can capture some of the salient features observed in history. This article refers only to models that concentrate on renewable resources since these are the most interesting and least understood as regards changes in population structures and dynamics. It starts by reviewing models of population and resource dynamics that refer to subsistence economies. Within this class of models it is possible to investigate how the equilibrium between the resource and population stock changes, dependent on the functional relations that govern the dynamics of population and resources. But as societies become less bound to the land, more urbanized, and more technological, resources might still be at risk, albeit no longer from positive population growth but rather from the environmental costs of consumption and production. To capture the impact of population growth on the environment, demographic impact models have been developed aimed at decomposing the effect on the environment from population on the one hand and that from consumption and technology on the other. The article concludes our review with a look at models of environmental influences on population dynamics.

Although the importance of the links between population and environment is widely appreciated, there is little agreement in the literature about the nature of these links.

The dynamic link between population and natural resources – influences are never entirely unidirectional or constant over time – constitutes the main difficulty in assessing formal models and unified theories. To complicate matters further, this interrelationship depends on the level and type of economic activities, technological development, institutional settings, and cultural systems. Even the variables themselves are not uniquely defined, but depend rather on the level and purpose of the analysis.

This article does not survey numerical simulation models of demographic/economic/environmental interactions (see Sanderson, 1994 for a review), of which the World 3 Model (Meadows et al., 1972) is the most popular. Instead, it looks at some simple mathematical models that capture stylized facts of the link between population and natural resource dynamics. Such 'mathematical cartoons' help us to explain and understand how various population and environmental characteristics might affect each other, and they can teach us how to respond most effectively to various demographic and environmental developments.

Although it was exhaustible resources that first received theoretical attention, this article concentrates on renewable resources since these are the most interesting and least understood as regards changes in population structures and dynamics. In contrast to nonrenewable resources, the use of which is controlled largely by market prices, renewable ones are very often open-access resources. The overuse of resources if property rights are absent or poorly defined is called the 'first tragedy of the commons' (Hardin, 1968) and can be corrected by restricting access to the resource. But as emphasized by Lee (1990), if the population is not fixed – as is presupposed in the models presented in this article – free access through reproduction constitutes the 'second tragedy of the commons'. More recently the externality of childbearing in relation to pollution externality has been studied in Harford (1997, 1998) and Schou (2002).

Malthusian Population Dynamics and Natural Resources

The study of interactions between population and resources has a long history. According to Malthus, population growth reduces material welfare due to diminishing returns to labor on a fixed supply of land. On the other hand the higher the level of material welfare the higher the population growth rate will be. The Malthusian model predicts that "population will equilibrate with resources at some level mediated by technology and a conventional standard of living" (Lee, 1986). Improvements in technology will be offset in the long run by increases in the size of the population, but the standard of living will not be related to the level of technology. As such, the Malthusian model provides a description of a rather primitive society with incomes not too far above the subsistence level and where local renewable resources are an important part of the economic production process.

Renewable resources (agricultural land, forests, lakes, etc.) are not in fixed supply as Malthus assumed. Renewable resources regenerate, but if the rate of utilization (harvest) exceeds the rate of regeneration, a renewable resource will be depleted or, in the extreme case, irretrievably exhausted. By adding the dynamics of renewable resource growth to the dynamics of population growth, the Malthusian model is capable of explaining patterns of population growth and resource degradation that do not necessarily end up in a single

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31005-4

equilibrium (Malthusian trap) (see Brander and Taylor, 1998; Prskawetz et al., 1994).

The structure of these models can best be described in terms of prey–predator dynamics, with the resources, R, being the prey and the population, P, acting as the predator. The dynamics of renewable resources (eqn [1]) is commonly described by the standard model of mathematical bioeconomics, where the net growth of the renewable resource, $\mathrm{d}R(t)/\mathrm{d}t$, is affected by two counteracting factors: indigenous biological growth, $g[R(t)]$, and the harvest, $H[R(t), P(t)]$, which depends on the stock of resources available to be harvested and the number of people who are harvesting. Indigenous resource growth is modeled by the logistic growth function $g[R(t)] = aR(t)[K - R(t)]$, where the coefficient K determines the saturation level (carrying capacity) of the resource stock (i.e., K is the stationary solution of R if the resource is not degraded) and parameter a determines the speed at which the resource regenerates. The functional form of the harvest function is determined by the prevailing economic structure, and it establishes the link between the stock of resources and population. The population growth rate, $(\mathrm{d}P(t)/\mathrm{d}t)/P(t)$ (eqn [2]), is modeled as an increasing function of material welfare $\gamma(t) = \gamma[P(t), H(t)]$, which is determined by the level of the harvest and will be reduced by population growth. Whenever material welfare falls below the subsistence level, the population will decline. These Malthusian population dynamics imply that population growth may well adapt to resource constraints in contrast to models with exogenous positive population growth, where the economy collapses if resources do not regenerate quickly enough.

$$\frac{\mathrm{d}R(t)}{\mathrm{d}t} = g[R(t)] - H[R(t), P(t)] \qquad [1]$$

$$\frac{\mathrm{d}P(t)}{\mathrm{d}t} = n[\gamma(t)]P(t) \qquad [2]$$

Within this class of models it is possible to investigate how the equilibrium between resources and population stock changes, dependent on the functional relations that govern the dynamics of population and resources. For instance, the efficiency of harvest technology, the degree of substitution between labor and resources, the indigenous rate of resource growth, and the carrying capacity of the resource stock will have an effect on material welfare and hence on population growth. In turn, fertility and mortality will affect the resource dynamics via the input of changing labor stocks in the harvest. An empirical calibration of the model for the case of the small Pacific Easter Island characterized by pronounced population fluctuations was carried out by Brander and Taylor (1998) in the framework of a general-equilibrium model.

During the last decade, the model by Brandner and Taylor has been extended in several directions. Dalton and Coats (2000) studied the introduction of different structures of property rights (common access vs personal ownership of resources) as represented by alternative specifications of the link between the dynamics of natural resources and population growth. Their results indicate that the steady-state solutions for population and resources are unaffected by the institutional setup, whereas the transition toward the long-run equilibrium will depend on the prevailing institutional setup exhibiting less (more) fluctuations in the dynamics of population and resources under private (common) property resources. These results will change if institutions also affect other parameters and functional forms of the model such as technology, preferences, fertility, and mortality (e.g., D'Alessandro, 2007). Institutional settings are also discussed in Anderies (2000); both for the Brandner and Taylor model of Easter Island as well as the model of the Tsembaga society of New Guinea (Anderies, 1998). The Tsembaga people is provided as an example, where institutional settings, such as a ritual cycle in which pigs are killed and warfare is initiated, serve to reestablish a sustainable equilibrium of population and resource stocks. Modifying the original Brandner and Taylor model by introducing a subsistence level of consumption, Anderies (2000) shows that changes in population and resources are more rapid as compared to the original Brandner and Taylor model. Anderies then argues that these sudden changes – that fit the historical evidence quite well – did not allow for institutional adaption. Explicit conservation policies (a consumption tax and quotas on total resource harvest, total harvest effort, and per capita harvest effort) are introduced in Pezzey and Anderies (2003). These policies may counteract the destabilizing effect of a larger subsistence level in consumption although their implementation and control may indeed be rather difficult. Besides institutional reforms, several authors have also studied the role of technological progress to prevent the collapse of population and resources in Easter Island. Reuveny and Decker (2000) assume that the growth rate of resources and their carrying capacity, as well as the productivity of harvesting positively depends on technological development. However, as technological progress may allow for faster population growth, it may thereby even foster the collapse of the resource stock and population.

An alternative explanation of the dynamics of population and resources in primitive societies such as Easter Island was proposed by Maxwell and Reuveny (2000). The authors refer to recent research on resource scarcity as it may initiate conflict in developing countries and extend this causal link by studying the repercussion of conflict situations on resource and population dynamics. A variant of the model by Maxwell and Reuveny can be found in Prskawetz et al. (2003). Instead of assuming two separate models that present either a conflict or no-conflict situation, they postulate that changes in the labor force participation rate, the death rate, and the growth rate of resources are 'smooth' functions of the prevailing level of per capita resources. Most recently de la Croix and Dottori (2008) explain the history of Easter Island by introducing a model of noncooperative bargaining between two competing groups where population growth acts as a means to gain power. Fertility behavior between both groups is therefore guided by strategic complementarities – a new motive to explain population dynamics. The authors discuss the conditions under which a population race may set in, which ultimately results in resource degradation and the collapse of the society. A recent review of the various extensions of the Brandner and Taylor model is presented in Nagase and Uehara (2011).

Contrary to the Malthusian predictions, increasing population densities might be beneficial, as argued by Boserup (1981), and could well increase the human carrying capacity of the earth. Higher population densities will initiate technological innovations in agriculture, thereby increasing the yields so that the natural environment can support a larger population without reducing the level of welfare. Similar positive feedback mechanisms are captured in a simple mathematical cartoon of the interdependence between the growth in population $P(t)$ and carrying capacity $K(t)$ (expressed in numbers of individuals) by Cohen (1995) as

$$\frac{\mathrm{d}P(t)}{\mathrm{d}t} = rP(t)[K(t) - P(t)] \qquad [3]$$

$$\frac{\mathrm{d}K(t)}{\mathrm{d}t} = c\left[\frac{\mathrm{d}P(t)}{\mathrm{d}t}\right] \qquad [4]$$

with $r > 0$ and c either negative, zero, or positive. The parameter c, which captures the effect of an increment of population on the carrying capacity, determines the long-term population dynamics, and it can represent technological innovation. When $c = 1$ population size grows exponentially (Euler, eighteenth century); when $c < 1$ population grows logistically (Verhulst, nineteenth century); and when $c > 1$ population grows faster than exponentially (Forester and coworkers, twentieth century). The positive correlation between population growth and technological progress is taken up by Dalton et al. (2005) who extend the model by Reuveny and Decker (2000) allowing for endogenous technological progress. Whether long-term economic growth with positive levels of populations and resources is viable depends on the division of technological progress between being 'resource-depleting' (by increasing the efficiency of harvest) or 'resource-conserving' (by increasing the growth rate of resources) (Dalton et al., 2005: p. 36).

Malthusian results (in the sense that population will grow to the point where material welfare matches subsistence demand) can be further undermined by allowing population growth to be a choice variable. Zero population growth may well be the optimal choice for individuals in the economy. Since environmental changes are often slow over the course of an individual life span, and since environmental damage may outlive its perpetrators, overlapping generation models (Eckstein et al., 1988) provide an appropriate demographic structure. Intra- as well as intergenerational conflicts can be modeled in such a framework, taking account of the effects of increases in population and resource exploitation on the future population's quality.

Economic Development and the Environment

The models presented in Section Malthusian Population Dynamics and Natural Resources represent traditional societies in which populations derive their living from primary occupations (agriculture, hunting, fishing, etc.) that depend on the availability of resources. But as societies become less bound to the land, more urbanized and more technological, they not only use the environment as a source of natural resources but also as a dump for waste products arising from human activity. Furthermore, an economy's production possibilities are no longer determined by the maximum sustainable yield of renewable resources. Improvements in technology can increase the sustainable yields or reduce the resource stock required for production, and economic growth will allow for the use of artificial capital in place of natural resources. In open economies with trade, technological change, and economic growth, there is no simple and direct relationship between population growth on the one hand and the environment on the other hand. The paper by Lehmijoki and Palokangas (2010) nicely demonstrates – based on a stylized dynamic optimization model – how gains from trade in developing countries may first increase and then decrease environmental pollution and population growth, thereby replicating the time path of the environmental Kuznets curve.

Resources might still be at risk, albeit no longer by positive population growth alone. The risk can stem from the environmental costs of consumption and production. It is therefore of great importance to understand how these environmental impacts depend on different population structures.

An interesting contribution that considers the role of consumption for environmental quality but also allows for investment to increase environmental quality is presented in John and Pecchenino (1994). Based on an overlapping generations model, where the utility of households depends on consumption and environmental quality, they study the link between economic growth and the environment. The short-lived agents may be better-off if a long-lived social planner takes into account the externalities of consumption and maintenance of the environmental quality. The model is extended to allow for population growth in John et al. (1995). Lower population growth together with lower levels of consumption are shown to imply higher levels of environmental quality and economic output in the steady state. Similar to John and Pecchenino (1994) the authors show that a social planner who has a lifetime similar to the environment may internalize the externalities that are not taken into account by short-lived individual households.

The role of preferences and technology in the relation between population size and environmental quality is studied in Cronshaw and Requate (1997) within a static framework, where agents' utility also depends on the aggregate emissions of the economy. The very long-term relation between energy use and economic development, allowing for endogenous population development, is studied in Fröling (2011) within the framework of the unified growth theory.

Besides the mere number or growth of the population, its age structure will be an important variable for long-term economic growth and the environment. Dalton et al. (2008) introduce population age structure into an energy-economic growth model. Calibrating their model to the US shows that population aging reduces long-term emissions and the effect may be similar to the role of technological change.

The Impact of Population on the Environment

In a seminal paper, Ehrlich and Holdren (1971) express the impact on the environment, I (e.g., the value of some

pollutant), as the product of population, P, and per capita impact, $F(P)$:

$$I = PF(P) \quad [5]$$

Depending on whether diminishing returns or economies of scale are dominant, per capita impact can be increasing or decreasing in the total population. The most familiar form of such a demographic impact model is the so-called I-PAT identity, which divides per capita impact $F(P)$ into affluence A, and technology T. The accounting model I-PAT stands for the environmental Impact decomposed into Population size P, Affluence A, and Technology T. Affluence can be measured as Gross National Product (GNP) per capita, and technology represents the mean impact of an extra dollar of production (impact/GNP). The latter variable encompasses the cleanliness of technology, the effects of institutions, and other factors that can alter the impact efficiency of production.

Demographic impact models (Wexler, 1996) constitute multiplicative identities aimed at decomposing the effect on the environment of population on the one hand and that of consumption and technology on the other. The number of variables on the right-hand side of eqn [5] can be any number greater than two. Although these models are commonly used, they face several criticisms. They suppress any feedback relation between the variables on the right-hand side; their implications are highly sensitive to the choice of decomposition variables; and the method of decomposition and the role of institutions and culture are ignored. Recent research on the I-PAT identity has dealt with some of these problems. Expressing the identity in terms of variances rather than means (Preston, 1996) allows one to incorporate the links between the decomposition variables. Considering households instead of individuals as the unit of consumption (MacKellar et al., 1995) highlights the effect of economies of scale as household size increases. Typical results of such analyses are that the population has a much stronger impact on the environment in developing countries than in developed countries. In the case of environmental hazards produced by industrial processes, population growth plays a minor role both in developing and in developed countries. A stochastic version of the I-PAT identity (STIRPAT) and a discussion among the alternative variants of measuring the impact on the environment are presented in York et al. (2003). STIRPAT constitutes a stochastic model and stands for Stochastic Impact by Regression on Population, Affluence, and Technology.

Milik et al. (1996) embed the I-PAT identity into a dynamic model where population P, affluence A, and technology T influence each other and vary over time. Pollution I reduces the regenerative capacity of natural resources, which in turn influences the dynamics of population and affluence. The model highlights the fact that understanding and monitoring the impact of pollution on the environment is important even when outward signs of damage (as a reduction in the resource stock) are not yet visible. Ecosystems often absorb stresses over long periods of time and then eventually reach a disruption level at which the cumulative consequences of stress appear in critical proportions. A policy of waiting until the first signs of environmental deterioration are observed before actions are taken to reduce the impact on the environment may well prove to be disastrous. When action is initiated, the impact on the environment might already be irreversible. Mathematically, these systems can best be described in terms of 'slow–fast' dynamics, where during certain periods some variables vary much more rapidly than others. While population and economic variables can be regarded as slow-moving variables, the environment changes most rapidly once the system has absorbed too much stress. For instance, the emission of carbon dioxide occurred almost unobserved for several decades before any attention was paid to the impact of greenhouse gases on global warming.

It becomes difficult to quantify the impact of population on the environment if the demand for local resources is not related to local population growth and if institutional environments are not stable. In fact, "commercialisation by converting a limited and inelastic subsistence demand to a limitless and elastic export demand (from the standpoint of the region, at least) can lead to much more rapid rates of exploitation than would be implied by population growth alone" (Repetto and Holmes, 1983).

Modeling Environmental Influences on Population Dynamics

Existing models of environmental influences on population exhibit two shortcomings. First, they generally do not distinguish between the separate effects the environment may have on fertility and mortality. Second, the environmental impact on population growth is commonly modeled to work only through the economic and social variables of the model. There are only few examples in the literature that model the direct effect of environmental stress on fertility and mortality.

The first example (Nerlove, 1991) is based on the vicious circle of poverty, population growth, and environmental degradation as evidenced in small rural communities of sub-Saharan Africa. In these economies simple tasks like fetching water and collecting fodder and wood are mostly carried out by children. This means that children are not only valuable to parents for future income but also as a source of current income. Higher population growth leads to more resource depletion, which reduces the marginal productivity of the resource. To offset this effect families have more children, thus depleting the resource even more. In a short parable, Nerlove demonstrates that increasing the birthrate when the environment deteriorates will be the optimal choice for a household that maximizes per capita harvest when 'the perceived marginal product of an additional child increases as environment deteriorates'. In addition, in a system in which land rights are acquired through cultivation, a large number of children can imply increased claim to land ownership. This positive feedback between fertility and environmental degradation is in stark contrast to Malthusian dynamics, where population equilibrates with resources. Since the marginal private and social costs of reproduction are not the same, Nerlove then shows how social interventions in the form of taxes or subsidies can be used to induce a specific birthrate corresponding to a socially desirable stationary state.

The underlying mechanism of the above-mentioned vicious circle is neither population growth nor environmental degradation but poverty, which prevents the substitution of

alternative fuel sources, and the low status of women and girls, which devalues the large amount of time and effort that they must devote to daily gathering activities. To escape this vicious circle one needs to alleviate poverty and educate women.

As suggested by Chu (1998), the increasing specialization and level of economic activity typical of advanced societies may also imply a substantial dependency of population dynamics on the state of the environment. Increasing the level of human activities destroys the earth's biodiversity, so that the ability of the environment to absorb negative shocks will decline, while increased specialization makes people less adaptive to environmental shocks. Chu suggests a simple mathematical model of the survival probability $f(\cdot,\cdot)$ to capture both effects:

$$\begin{aligned} f(m_t, x_t) &< f(m_t', x_t) \quad \text{if } x_t > 0 \\ f(m_t, x_t) &\geq f(m_t', x_t) \quad \text{if } x_t \leq 0 \end{aligned} \qquad [6]$$

where m_t denotes the logarithm of the number of intermediate goods (a measure of the division of labor) with $m_t < m_t'$ and x_t is a realization of the environment value X_t with the critical state $x_t = 0$. The mean and the variance of the random variable X_t will be increasing functions of m_t. By reducing the ability to adapt, increased specialization m_t' will decrease the survival probability if the environment is already in a disastrous state $x_t < 0$, while the opposite relation will hold if the environmental state is favorable $x_t > 0$. These considerations are integrated into a modern Malthusian theory in Chu and Tai (2001).

In a recent contribution Mariani et al. (2010) consider the role of environmental quality for life expectancy. Their model is based on previous work by John and Pecchenino (1994) but accounts for the empirically observed positive correlation between life expectancy and environmental quality. More specifically they assume an overlapping generation framework where individuals live for three periods. While survival into the first and second period is quite certain, the survival into the third period is uncertain and depends on environmental quality. During their second period of life, individuals choose consumption and environmental maintenance (given an exogenous wage rate) such as to maximize their utility – which positively depends on second-period consumption and third-period environmental quality – and taking into account the effect of consumption and environmental maintenance on the dynamics of environmental quality. The model is capable of capturing the stylized facts of the positive correlation between survival and environmental quality. In addition, the authors show that multiple equilibria are possible that represent environmental poverty traps with low life expectancy and low environmental quality as opposed to high-level equilibria with high life expectancy and high environmental quality. The results are robust toward the extension of endogenous human capital formation that spurs growth and also life expectancy.

Another recent contribution that endogenizes the role of pollution on mortality is Lehmijoki and Rovenskaya (2010). Based on a long-term consumer optimization model and the assumption that pollution as a by-product of production negatively affects survival, the authors study the role of economic growth for reduced pollution and lower mortality.

Concluding Assessment of the Literature

Although there is a growing awareness of the population/environment linkage, as evidenced by the increasing number of empirical (case) studies, research has only slowly progressed in the Malthusian spirit of modeling the complex interaction in simple mathematical cartoons. Often dynamic interactions between population and environment are neglected – or increasingly complex simulation models are set up where anything can happen.

Further research on this topic is needed. The concern should be shifted away from physical limits to growth toward the ability of social units to respond to environment/population linkages. Although they are more difficult to formalize, such models should also include organizational and institutional issues.

Population Dynamics: Momentum of Population Growth

Thomas J Espenshade and Jonathan BC Tannen, Princeton University, Princeton, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by Y.J. Kim, volume 17, pp. 11766–11769, © 2001, Elsevier Ltd.

Abstract

This article summarizes the recent literature on population momentum, usually defined as the subsequent population growth or decline after replacement conditions have been achieved. We review total momentum, its constituent parts (nonstable and stable momentum), trends over time, and how momentum is affected by immigration and emigration. Numerical examples are provided. The unifying concept is that momentum is created by a deviation between a population's observed age distribution and its underlying stationary (or sometimes stable) age distribution, especially at younger ages.

Introduction

It is natural to assume that, in a closed population, the rate of population growth is determined by the level of fertility and mortality. After all, the observed growth rate at time t, $r(t)$, is simply the difference between the crude birth rate, $b(t)$, and the crude death rate, $d(t)$, or

$$r(t) = b(t) - d(t)$$

It is true that in a long run stable equilibrium population the intrinsic growth rate, r, depends only on the fertility schedule, $m(a)$ – the annual rate of bearing daughters for women at exact age a; and on the survival function, $p(a)$ – the probability of surviving from birth to exact age a, given the underlying force of mortality schedule, $\mu(a)$ – the annual rate of dying for women at exact age a. In the short run, however, the shape of the current age distribution also matters.

If the proportion of women in the female population at age a and time t is given by $c(a, t)$, then

$$b(t) = \int_0^\omega c(a,t)m(a)\mathrm{d}a$$

where ω is the oldest age attained, and

$$d(t) = \int_0^\omega c(a,t)\mu(a)\mathrm{d}a$$

so that

$$\begin{aligned} r(t) &= \int_0^\omega c(a,t)m(a)\mathrm{d}a - \int_0^\omega c(a,t)\mu(a)\mathrm{d}a \\ &= \int_0^\omega c(a,t)[m(a) - \mu(a)]\mathrm{d}a \qquad [1] \end{aligned}$$

The term in square brackets in eqn [1] is negative below the age when childbearing begins (α) and above the age when it ends (β), and is usually positive in between. This means that all other things being equal, the so-called middle-heavy age distributions that have relatively large numbers of women at or near the peak ages of childbearing tend to maximize population growth rates. Even when a schedule of fertility at replacement, $m_0(a)$, is substituted for $m(a)$ in eqn [1], the rate of population growth at time t will not necessarily be zero, unless $c(a, t)$ is the age distribution of the stationary population.

Here is where the idea of population momentum enters. Equation [1], with $m_0(a)$ substituted for $m(a)$, shows the contribution of age composition to population growth in a given year t when fertility is at replacement. Population momentum measures the cumulative contribution of age composition to population growth (or decline) in all future years after fertility has been set at replacement.

Total Population Momentum

An Empirical Approach

A population typically does not stop growing or declining the instant its fertility reaches replacement level. Instead, in a closed population, growth or decline slows gradually until a zero-growth stationary population is reached, in much the same way that a car gradually comes to a complete stop after the driver's foot is lifted from the accelerator (Schoen and Kim, 1991). The amount of momentum contained in a population's age distribution is usually measured in a relative sense by the ratio of the size of the long-run stationary population to that of the observed population when replacement fertility is first attained. Momentum coefficients in AD 1935 ranged from 1.08 in Austria, Belgium, and France to 1.60 in Puerto Rico and Honduras (Vincent, 1945). In AD 2005, momentum coefficients among United Nations countries fell between a low of 0.81 for Bulgaria and a high of 1.76 in Oman (Espenshade et al., 2011). Coefficients of momentum can be greater than 1.0 (indicating positive momentum) or less than 1.0 (when momentum is negative). Momentum can play a large or a small role in population dynamics (Bongaarts, 1994, 2007).

It may seem paradoxical that population growth (or decline) does not necessarily cease the moment replacement fertility is reached. Consider two examples. Suppose, first, the case of a rapidly growing population in which the total fertility rate (TFR) has been above five for the past several generations. In this situation, young daughters are numerous relative to the number of mothers, and mothers are in plentiful supply relative to the number of grandmothers. Now suppose that fertility is suddenly reduced to replacement and the net reproduction rate (NRR) is 1.0. Going forward, girls in the population who have

not yet entered childbearing will have only enough daughters to replace themselves, so that eventually there will be roughly equal numbers of young daughters and mothers (allowing for mortality). But the population of grandmothers swells in the short run as their relatively more numerous daughters age into their later years (Preston, 1986). The total population continues to grow for a while after fertility has been lowered, and the growth is largely concentrated at the older ages.

Alternatively, consider a population that has experienced a sharp fertility decline to below replacement levels, or one where, hypothetically, fertility has been below replacement for a very long time. Children in this population are likely to be relatively few compared to the number of mothers. If fertility is raised instantaneously to replacement, then going forward these children will replace themselves as they move through their childbearing years. But when they age into their later years, they will succeed larger cohorts of their mothers. The ensuing population decline will be largely concentrated at the older ages.

These two situations are illustrated in Table 1, which contains data for the female populations of Nigeria and Bulgaria. Nigeria's female population in the mid 2010s totaled 78.2 million. Its TFR for the previous 5 years was 5.61; and this high level of fertility had been sustained for many years, with only small declines from above 6.0 in the past decade (United Nations, 2011). The population is approximately stable, as indicated by the similarity of the observed annual rate of population growth (2.56%) compared to the intrinsic growth rate (2.49%). Nigeria's coefficient of population momentum for AD 2010 was calculated by projecting the AD 2010 population forward 300 years by which time a stationary population had been achieved, using observed rates for AD 2005–10 and then setting fertility to replacement by normalizing the maternity schedule by the NRR. A stationary population with 114.0 million women implies a momentum coefficient of 114.0/78.2 = 1.457. The impact of age composition alone is sufficient to propel population growth, resulting in an eventual stationary population nearly 46% larger than the observed population in 2010. It is clear from Table 1 that this growth is not shared equally by all age groups, but is concentrated above about age 30.

Bulgaria, also shown in Table 1, represents a country with a dramatic fertility collapse. As recently as AD 1985–90, Bulgaria's TFR was 1.92, just below replacement, and it had been comfortably above replacement for most prior years dating back to AD 1950. But the TFR fell to 1.51 in AD 1990–95 and further to between 1.2 and 1.3 for the period AD 1995–2005. By AD 2005–10 it had rebounded slightly to 1.46 (United Nations, 2011). This fertility decline is reflected in Bulgaria's female age distribution for AD 2010. Just 12.9% of its population is under age 15 years, compared to 42.4% in Nigeria. The observed annual growth rate was −0.59% and the intrinsic rate was −1.36%. The momentum coefficient for Bulgaria shows that, even if fertility were raised immediately to replacement and remained fixed, the female population would nevertheless decline from 3.9 million in AD 2010 to 3.0 million – a decline of more than 22%. The overall momentum coefficient is 0.777, but the values for individual age groups indicate that, as anticipated, the shrinkage is confined to ages 20 years and above.

An Analytic Approach

The previous discussion has suggested that what determines total population momentum is the shape of a population's observed

Table 1 Population momentum values for Nigerian and Bulgarian females, 2010[a]

	Nigeria			*Bulgaria*

age distribution in relation to the age distribution of the long-run stationary population. Young populations, especially those with high proportions below age 15 years, tend to have a substantial amount of built-in positive momentum, whereas older populations with relatively few children typically have latent population decline even after fertility is raised to replacement.

These notions are formalized in the following analytic expression for total population momentum (Espenshade et al., 2011).

$$\text{Total Momentum} = \int_0^\beta \frac{c(x)}{c_0(x)} \int_x^\beta p(a)m_0(a)\mathrm{d}a\mathrm{d}x/A_0 \qquad [2]$$

where $c(x)$ is the observed proportionate age distribution, A_0 is the mean age of childbearing in the long-run stationary population, and $c_0(x)$ and $m_0(a)$ are the stationary population counterparts to $c(x)$ and $m(a)$. The subscript 0 is used here to indicate replacement values in the stationary population where $r = 0$ by definition. An identical formula for total momentum appears in Preston and Guillot (1997: pp. 20–21), and it was anticipated in somewhat different form by Keyfitz (1985: pp. 155–157).

Equation [2] shows that relative deviations between a population's observed age distribution, $c(x)$, and its stationary population age distribution, $c_0(x)$, below the oldest age of childbearing, β, largely determine population momentum. Young populations (in relation to their stationary forms) will contain large amounts of positive momentum; whereas populations with relatively few young people in relation to the stationary population will have negative momentum. In addition, the second integral in eqn [2] is a weighting function. These weights sum to unity and are greatest before the onset of childbearing. Therefore, the deviations between $c(x)$ and $c_0(x)$ that matter most are those that occur at the youngest ages. Finally, it is apparent from eqn [2] that if the observed population is already stationary so that $c(x)/c_0(x) = 1.0$ everywhere, then the coefficient of momentum is identically 1.0 because all momentum has been wrung out of the age distribution (Espenshade et al., 2011; Preston and Guillot, 1997).

Disaggregating Population Momentum

Nonstable Momentum

Total population momentum, or the cumulative contribution of age composition to the change in future population size, has two principal parts. The first part involves the transition to a stable equilibrium population. Imagine an initial arbitrary female population with size P and proportionate age distribution $c(x)$. We know from eqn [1] that the observed rate of population growth is influenced by the shape of $c(x)$ along with patterns of fertility and mortality. Let the contribution of fertility and mortality to $r(t)$ be captured by the intrinsic growth rate, r. Then the residual $r(t) - r$ measures the contribution of age composition at time t. If fertility and mortality are held constant, $r(t)$ will converge to r. But in the meantime, the population grows or declines due to age composition alone at rate $r(t) - r$. By the time $r(t) = r$ so that $r(t) - r = 0$, the population will have reached size Q due solely to the effects of age composition.

Q will be a stable population. In fact, it is called the stable equivalent population, because if populations P and Q are projected forward using fertility and mortality observed at time $t = 0$, they will eventually become indistinguishable in terms of size, age composition, and rate of growth (or decline). Another way to see how Q is determined is to imagine projecting population P forward using constant fertility and mortality until it becomes a stable population, and then reverse projecting the resulting stable population back to time $t = 0$ using the intrinsic growth rate, r.

The first part of total population momentum, then, is the ratio Q/P. It is called 'nonstable' momentum. It is the transient or ephemeral part of total momentum, because it becomes smaller and smaller (and eventually disappears) as the initial population P gets closer to a stable population. If P were stable to begin with, then $P = Q$, and there would be no nonstable momentum.

Formally, nonstable momentum can be written as

$$\begin{aligned}\text{Nonstable Momentum} &= \frac{Q}{P} \\ &= \int_0^\beta \frac{c(x)}{c_r(x)} \int_x^\beta e^{-ra} p(a)m(a)\mathrm{d}a\mathrm{d}x/A_r\end{aligned} \qquad [3]$$

where $c_r(x)$ is the stable age distribution corresponding to intrinsic growth rate r, and A_r is the mean age of childbearing in the stable population (Espenshade et al., 2011). Nonstable momentum is a weighted average of relative deviations between the observed age distribution and the implied stable age distribution. Because the weights (in the second integral) are nonincreasing, the deviations that matter most are those in the early years of life before childbearing begins. The importance of nonstable momentum has been recognized by Bourgeois-Pichat (1971), Espenshade and Campbell (1977), Feeney (2003), and Schoen and Kim (1991).

Stable Momentum

Instead of starting with an arbitrary female population at time $t = 0$, suppose we begin with a stable population (for example, population Q). Now find momentum in the usual way by setting fertility at replacement, holding fertility and mortality constant, and projecting the population until it becomes stationary with eventual constant size S_2. Then stable momentum is the ratio S_2/Q, or,

$$\begin{aligned}\text{Stable Momentum} &= \frac{S_2}{Q} \\ &= \int_0^\beta \frac{c_r(x)}{c_0(x)} \int_x^\beta p(a)m_0(a)\mathrm{d}a\mathrm{d}x/A_0\end{aligned} \qquad [4]$$

It is called 'stable' momentum because, just like other stable population concepts, it depends only on fertility and mortality schedules and not on the current age distribution (Espenshade et al., 2011). The value for stable momentum will depend on relative deviations between the stable and stationary age distributions, with the youngest ages carrying the most weight.

Keyfitz (1971) popularized the concept of population momentum in a stable population. He showed that, starting with a stable population, total momentum is the ratio

$$\frac{S_2}{Q} = \frac{b\mathring{e}_0}{rA_0R_0}(R_0 - 1) \qquad [5]$$

where b is the stable birth rate, R_0 is the initial NRR, and $\mathring{e}_0$ is life expectancy at birth. It is straightforward to see that eqns [4] and [5] are identical. Alternative formulations for momentum in initially stable populations have been proposed by Goldstein and Stecklov (2002), Kim and Schoen (1993, 1997), and Schoen and Jonsson (2003). Some of this work assumes that fertility moves gradually (and not instantaneously) to replacement.

Fitting the Pieces Together

Return to the initial, arbitrary population P and recall how total momentum is calculated. Put fertility at replacement, hold fertility and mortality constant, and project P until it becomes stationary with size S_1. Total momentum is then S_1/P. The identity

$$S_1/P \equiv Q/P \times S_2/Q \times S_1/S_2$$

tells us that total momentum can be factored into the product

$$\text{Total Momentum} \equiv \text{Nonstable Momentum} \times \text{Stable Momentum} \times S_1/S_2 \qquad [6]$$

where S_1/S_2 is an offset factor. But if $S_1 = S_2$ we would have achieved an exact factorization of total momentum into the product of nonstable and stable momentum.

On the basis of an analysis of 176 UN countries, Espenshade et al. (2011) concluded that S_1 and S_2 are almost identical. In roughly 40% of the cases, the deviation was less than ±0.1%. In two-thirds of all cases, the deviations were contained within ±0.2%. And in three-fourths of all cases, the relative difference between S_1 and S_2 lay within ±0.3%. One implication is that the product of nonstable and stable momentum is an extremely good approximation to total momentum. More important, the identity in eqn [6] provides a unifying framework within which the types of momentum that various authors have considered can be situated.

There are several special cases in which S_1 is identically equal to S_2 – if the initial population is already stable or if current fertility is already at replacement. Finally, there is the degenerate case where fertility is at replacement and the population is stationary. In this instance, there is no momentum of any kind: neither total, nor nonstable, nor stable (Espenshade et al., 2011).

There are distinct regional patterns for total momentum and its constituent parts. Total momentum in AD 2005 for more-developed countries (MDCs) was typically near 1.0 and frequently below it, whereas total momentum for the least-developed countries (LDCs) clustered around 1.5. Stable momentum was usually below 1.0 and often near 0.5 for MDCs, but close to 1.5 for LDCs. Nonstable momentum, on the hand, was near 1.5 for MDCs but closer to 1.0 for LDCs. Other developing countries had momentum values intermediate between those for MDCs and LDCs. This analysis shows that as the level of development increases, overall momentum values fall, nonstable momentum becomes stronger, and stable momentum grows weaker (Espenshade et al., 2011).

Population Momentum Over Time

Population momentum is usually considered as a static concept, calculated for a given point in time. Blue and Espenshade (2011) describe the arc of momentum over time in 16 populations, selected to represent different stages of the demographic transition. These stages are divided into five categories: (1) pretransition, when birth and dates rates are uniformly high, (2) early transition, with falling mortality and still relatively high fertility, (3) mid-transition, characterized by a robust rate of natural increase and the maximum difference between birth and death rates, (4) late transition, when falling fertility approaches low mortality, and (5) the second demographic transition, with low birth and death rates, and subreplacement fertility.

It is difficult to identify today any national population that falls into Stage 1 of the demographic transition, because no country remains untouched by improvements to mortality. There are, however, numerous examples of countries in each of the four later stages. Blue and Espenshade (2011) rely for their examples on Ethiopia, Haiti, Kenya, and Nigeria for Stage 2, on Egypt, India, and South Africa for Stage 3, on Argentina, Brazil, Indonesia, and Turkey for Stage 4, and on Belgium, Finland, France, Japan, and Sweden for Stage 5.

Measures of total population momentum, calculated at 5-year intervals starting as early as reliable data permit and continuing with projected data to AD 2050, support the following conclusions. Especially for the examples from developing countries, total momentum tends to rise at the beginning of the period of observation as mortality decline (with nearly constant fertility) creates a younger observed population and an older stationary population, thereby widening relative deviations between $c(x)$ and $c_0(x)$. Later, as fertility falls, total momentum also falls. Toward the end of the transition, if fertility appears to stabilize at below-replacement levels, then total momentum values stabilize below 1.0.

In particular, results for all 11 developing countries that comprise the examples for transition Stages 2, 3, and 4 are quite similar. In each case, total momentum tends to peak in an interval between 1.4 and 1.6. The main difference among the stages is in the timing of transition. The peak occurs about AD 1980 for countries in Stage 4, about AD 1995 for Stage 3 countries, and is projected to arrive about AD 2015 for countries now in the earliest stages of the demographic transition. For the five developed countries in Stage 5, the patterns are less uniform. The transition occurred more gradually, and therefore the rise and fall in total momentum also occurred more slowly. In addition, the peak momentum value for Stage 5 countries tends to be no higher than about 1.2. Japan appears to be a conspicuous outlier. Total population momentum was about 1.4 for Japan in AD 1950. But because of Japan's sudden fertility collapse, total momentum fell to roughly 0.8 by AD 2000 and is projected to decline further to close to 0.6 by AD 2045.

Blue and Espenshade (2011) also traced the evolution of stable and nonstable momentum in these 16 countries. If we imagine values for stable momentum graphed along a horizontal axis and those for nonstable momentum along a vertical axis, then demographic transition theory predicts that coordinates for stable and nonstable momentum will emanate from the origin (a value of 1.0 for both stable and nonstable momentum), form a counter-clockwise swirl pattern, and eventually return back to the origin (if fertility at the end of the demographic transition returns to replacement level) or to a point on the horizontal axis to the left of the origin if end-of-transition fertility stabilizes below replacement. Developing countries may exhibit larger swirls than those in developed countries because the former typically pass through the demographic transition more quickly.

The evidence we have supports the counter-clockwise swirl pattern for developing countries (especially those not hit hard by HIV), because these countries have largely avoided major fertility reversals. For example, we pick up the data for India in AD 1950 when stable momentum is 1.24 and nonstable momentum is 0.96. The curve then heads off to the Northeast until AD 1975, when total momentum reaches 1.5, stable momentum equals 1.43, and nonstable momentum is 1.05. From that point, the curve changes direction heading in a Northwesterly direction until AD 2030 when stable momentum will have fallen back to 0.82 and nonstable momentum is at its maximum (for India) of 1.44. Beyond that point, the momentum swirl heads southward. There is little further change in stable momentum, though nonstable momentum declines to 1.21 by AD 2050. Developed countries tend to follow this pattern, too, but only up to about AD 1950. The ensuing fertility swings from the baby boom inject some jagged fluctuations into these patterns along a vector running from the Northwest to the Southeast.

Population Momentum Incorporating Migration

This section draws on recent work by Espenshade and Tannen (2013). Discussions of population momentum typically assume a closed population. When these models are extended to include immigration and emigration, however, new possibilities emerge. In this expanded context, a given population can be associated with a range of momentum values depending on how the task of reaching replacement conditions is shared between fertility change and immigration change.

In the expanded framework, the survival function is no longer the survival function, $p(a)$, described above. Instead, one can exit a population by dying or by emigrating, and one can enter by immigrating above age 0. To accommodate these possibilities define a migration-inclusive survival function $\pi(a)$ as

$$\pi(a) = e^{-\int_0^a (\mu(x)+\nu(x)-\iota(x))\mathrm{d}x} \qquad [7]$$

with mortality rates $\mu(x)$, in-migration rates $\iota(x)$, and out-migration rates $\nu(x)$. Notice that, unlike $p(a)$, $\pi(a)$ can increase over some age intervals if the immigration rate exceeds the sum of mortality and out-migration rates, and it can even exceed 1.0. But eventually $\pi(a)$ must return to zero. If we define maternity rates $m(a)$ as before, then a population of size P with proportionate age structure $c(x)$ has an intrinsic growth r^* that satisfies

$$\int_0^\beta e^{-r^* a}\pi(a)m(a)\mathrm{d}a = 1 \qquad [8]$$

In closed-population scenarios, replacement fertility is generally achieved by dividing the maternity schedule by the NRR, effecting the same proportionate fertility change (higher or lower) at all ages. Here, if replacement conditions are attained entirely through adjustments to fertility, suppose fertility is modified according to

$$m_0(a) = e^{-r^* a}m(a)$$

Alternatively, suppose fertility is left unchanged and the immigration rate schedule is moved up or down by a constant amount r^* at all ages to achieve replacement. In particular, let

$$\begin{aligned}\pi_0(a) &= e^{-r^* a}\pi(a)\\ &= e^{-\int_0^a (\mu(x)+\nu(x)-[\iota(x)-r^*])\mathrm{d}x}\end{aligned}$$

These two extreme cases can be combined into a set of fertility and migration-inclusive survival functions that together achieve replacement. There are, in fact, many such combinations that jointly satisfy replacement conditions. Define new replacement-level fertility and migration-inclusive survival functions as

$$m_0(a|\gamma) = e^{-(1-\gamma)r^* a}m(a) \qquad [9]$$

$$\pi_0(a|\gamma) = e^{-\gamma r^* a}\pi(a) \qquad [10]$$

where γ is a parameter that ranges between 0 and 1 and represents the proportion of the overall rate change absorbed by immigration. If $\gamma = 0$, then all of the work of reaching replacement is being done by fertility. If $\gamma = 1$, then all of the adjustment to replacement falls on immigration. When these two new schedules are used in tandem, they imply a migration-inclusive intrinsic growth rate r^* equal to zero.

In the context of open populations that incorporate migration, two aspects of the long-run stationary population need to be examined: the shape of its age distribution and its size. Both will depend on the particular value assigned to γ. The age distribution is

$$\begin{aligned}c_0(a|\gamma) &= b_0(\gamma)\pi_0(a|\gamma)\\ &= b_0(\gamma)e^{-\gamma r^* a}\pi(a)\end{aligned} \qquad [11]$$

where $b_0(\gamma)$ is the birthrate in the migration-inclusive stationary population and equal to $1/\int_0^\omega \pi_0(a|\gamma)\mathrm{d}a$.

How the age distribution responds to changes in γ will depend on the value of r^*. The age distribution becomes younger as γ varies from 0 to 1 whenever $r^* > 0$. For example, Iceland in AD 2008 had a value for $r^* = 0.015$. As γ increases from 0 to 1, the share of Iceland's migration-inclusive stationary population that is under age 15 years rises from 11.7 to 20.2%, while the share over age 75 years falls from 16.2 to 8.7%. On the other hand, if $r^* < 0$, then the stationary population becomes older with increases in γ. Germany had a negative r^*-value in AD 2009 of -0.011. As γ ranges from 0 to 1, the share of Germany's stationary

population over age 75 years rises from 13.5 to 20.9%, while the percentage under age 15 years falls from 16.9 to 10.6. In the special case where $r^* = 0$, the shape of the stationary age distribution is invariant with respect to changes in γ.

Extending work by Preston and Guillot (1997) and Espenshade et al. (2011), we may define migration-inclusive momentum for a population with size P and age structure $c(x)$ as

$$M(\gamma) = \frac{S(\gamma)}{P} = \int_0^\beta \frac{c(x)}{c_0(x|\gamma)} \int_x^\beta e^{-r^* a} \pi(a) m(a) \mathrm{d}a \mathrm{d}x / A_0 \quad [12]$$

where $S(\gamma)$ is the size of an eventual stationary population that is achieved after converting fertility and immigration instantaneously to γ-dependent replacement, and then holding fertility, mortality, and both in-migration and out-migration rates constant until an equilibrium stationary population is reached. A_0 is the mean age of childbearing in the long-run stationary population. Equation [12] indicates that γ influences total momentum only through the shape of the stationary population age distribution. The form of eqn [12] is much like eqns [2]–[4]. Total momentum in the migration-inclusive case is once again a weighted average of age-specific relative deviations between the observed age distribution and the long-run migration-inclusive stationary population age distribution, with weights that are largest below the beginning of childbearing and decline toward zero with advancing age.

Equation [12] also shows that, unlike the closed-population example, a given open population will typically have many different coefficients of momentum associated with it, depending upon the particular value assigned to γ. Moreover, when $r^* > 0$, $c_0(x|\gamma)$ becomes younger as γ increases, and, consequently, total momentum falls. To take the case again of Iceland in AD 2008 with an r^*-value of 0.015, total momentum declines from 1.66 to 1.08 as γ increases from 0 to 1. On the other hand, for negative values of r^*, total momentum rises as γ increases. In the case of Germany in AD 2009, for instance, migration-inclusive momentum goes up from 0.87 to 1.25 when γ ranges from 0 to 1. Finally, if $r^* = 0$, then the stationary population age distribution is invariant with respect to changes in γ, and total momentum will not change.

Espenshade and Tannen (2013) analyzed data for all European Union countries having complete fertility, mortality, immigration, and emigration data. Two important policy lessons can be drawn from their analysis. First, depending on how replacement conditions are achieved and, therefore, on the value of γ that is chosen, in roughly two out of every five of their 58 country-year observations, the long-run stationary population size can be larger or smaller than the current population size. There are 34 instances in which population momentum was consistently positive, that is, in which momentum coefficients were always greater than 1.0. In some cases, the variation in momentum was relatively small, as in the case of Denmark in AD 2010 (1.055, 1.059) or the Netherlands in AD 2009 (1.087, 1.105). But in others, as γ ranges between 0 and 1, there can be wide swings in momentum, as in Iceland AD 2008 noted above (1.082, 1.663) or in Luxembourg AD 2008 (1.096, 1.816). However, there are 24 country-year observations – 41% of the total – for which momentum can be positive or negative depending on the choice of γ. In Lithuania in AD 2010, for instance, migration-inclusive momentum is 0.57 when $\gamma = 0$, but 1.39 when $\gamma = 1$. With such wide variation, policymakers have considerable leeway when developing judgments about future population size and age composition.

Second, migration-inclusive population momentum is often grossly underestimated by total momentum calculated for a closed population, at least for these European Union countries. In almost 60% (34 out of 58 cases) of the country-years for which the Espenshade and Tannen (2013) study provides data, the value for closed-population momentum falls short of the open-population momentum range, and it does so by a substantial margin two-thirds of the time. Moreover, in slightly more than half of these cases (18 out of 34), both high and low open-population estimates suggest that momentum is positive, whereas the closed-population estimate points in a negative direction. Therefore, in 31% of all cases, both the magnitude and the direction of the closed-population momentum estimate give misleading information.

Future Research

Several new research directions are suggested by the current state of our knowledge. First, typically in closed populations, momentum estimates are produced by reducing fertility immediately to replacement by dividing the maternity schedule by the NRR. Mitra (1976) proposed moving to replacement by an abrupt, but exponential, fertility decline. Other authors have examined the effects of a gradual shift to replacement fertility (Frauenthal, 1975; Goldstein, 2002; Goldstein and Stecklov, 2002; Li and Tuljapurkar, 1999, 2000; O'Neill et al., 1999; Schoen, 2005; Schoen and Jonsson, 2003; Schoen and Kim, 1998). It may be useful to investigate gradual transitions to replacement in fertility–migration combinations.

Second, Rogers (1975) outlined a framework for thinking about population momentum in a multiregional setting. Rogers (1995), Rogers and Willekens (1978), and Schoen (2002, 2006) applied this framework to investigate momentum in a two-region, urban–rural context. Typically in this work, the fertility schedule bears the full responsibility for getting to replacement. It is worth extending the analysis to let fertility and migration rates share this responsibility in some proportion. In addition, Raymer et al. (2012) propose three alternatives for incorporating flows of international migrants into multiregional models. One alternative that they do not consider, but that may be worth examining, is simply to expand an N-dimensional multiregional system to $N + 1$ dimensions to incorporate the 'rest of the world'.

Third, analyses of stable and nonstable momentum have so far been limited to single-region, closed populations. It would be productive to study the behavior of these two constituent parts of total momentum in a multiregional setting.

Acknowledgments

Population Dynamics: Probabilistic Extinction, Stability, and Explosion Theorems

Peter Jagers, Chalmers University of Technology, Gothenburg, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The relation between individual reproduction and the probability that populations die out is given. Populations that decrease on average will, of course, always die out, but populations whose expected sizes grow can also have a high probability of extinction. Malthus's law of exponential growth of populations, i.e., not dying out, holds in general, not only for populations of independently reproducing individuals, but also under some types of interaction. The stable age distribution and general stable composition, appearing as a consequence of exponential growth, are described. Finally, populations whose size and composition may influence individual reproduction are described.

Extinction, Stable Size, or Explosion?

Historically, probabilistic population theories originate from the *extinction problem*: suppose you know the probabilities of begetting 0, 1, 2, 3, … children. Now determine the probability that a population of a known number of individuals will eventually die out. Already Malthus had noted that a rapid increase of the whole population could occur together with frequent extinction of the separate families constituting the population. Rephrased in the terminology of evolutionary biology, frequent extinction of species does not contradict a rapid growth of the biomass of the world.

The mathematical explanation of this apparent paradox is due to Bienaymé (1845) and independently, 30 years later and only in parts correctly, to Galton and Watson, who were later to lend their names to the simplest, generation-counting version of the so-called branching processes that provide the mathematical structure underlying most stochastic population dynamics. Indeed, if p_k denotes the probability of giving birth to k children, $k = 0, 1, 2, 3, \ldots$, then the extinction probability of a population stemming from one ancestor will be the smallest nonnegative solution q of the equation,

$$\sum_k p_k q^k = q.$$

If we disregard the trivial case $p_1 = 1$, q will equal 1 if and only if the mean number of children,

$$m = \sum_k p_k k \leq 1.$$

If $m > 1$, then the population growth rate per generation will be m, and even though q must be less than 1 it can still be pretty large: it is easy to formulate demographically or biologically plausible cases, where, say, m exceeds 2 and q is still around 0.8.

The preceding argument presumes that individuals reproduce independently of one another. In deterministic population theories dependence structure is not made precise, and stable population sizes can arise, cf Keyfitz 1968. The situation in stochastic models with interaction or dependence upon the population as a whole is therefore of great interest.

Population Growth

To describe population growth in real time rather than generation-wise, a more sophisticated description of individual life and reproduction is needed. Probabilistic population dynamics is *individual-based* in the sense that it starts from such a description. Deterministic theories, on the other hand, often start directly from an assumed behavior of the population as a whole. Demographic theory is often *pseudo-probabilistic*, in that, it uses probabilistic notions but makes conclusions only about the expected behavior of the population as a whole. (This is the reason why there exist deterministic populations with stationary sizes: if the underlying stochastic population is critical in the sense that on average each individual is replaced by one child, then the expected total population size will be stationary, whereas the population itself will die out sooner or later.)

The most general probabilistic formulation of individual life goes as follows: at birth an individual inherits a *type* from her mother. The type determines her survival distribution as well as the distribution of age at childbearing. It also determines the types of the children she will give birth to in her turn. (Think of the type as a genotype, or a genotype combined with the social and biological conditions of life.)

In the *supercritical* case, where there is a positive chance of nonextinction, the probability laws of survival and childbearing determine a positive *Malthusian* parameter that gives the rate of exponential growth. In the theory of branching processes this rate is usually denoted by α, so that the population will grow like $e^{\alpha t}$, as time t passes. In deterministic theory the conventional notation is often r instead.

Reproduction Influenced by the Population as a Whole, Extinction or Quasi-Stationarity

Now assume that individual reproduction can be influenced by the present state of the population as a whole, its size or its

composition or both, or only by special individuals like neighbors or close relatives.

If this is the case, the situation can be drastically different and it is easy to exhibit examples of populations with high growth rate ($m > 1$), which still are bound to extinction (Haccou et al., 2005). It can, however, be proved very generally that a stochastic population, which is not dying out, must grow beyond all limits (Jagers, 1991; see also Haccou et al., 2005). This is a consequence of stochasticity and the asymmetry between extinction and big sizes: however big the population, there remains an albeit small but still positive risk of extinction, whereas an extinct population cannot be resurrected.

Even though exponential growth appears to be a consequence of the independence assumed (tacitly or explicitly) between the reproduction of different individuals, it is interesting to note that such growth has been proved also to occur in many cases where individual reproduction depends upon the population as a whole, e.g., its size. For such results in the case of simple Galton–Watson branching processes, see Klebaner (1984). In cases where the reproduction approaches criticality as the population grows, nonMalthusian growth can occur nevertheless, e.g., in the form of linear growth (Klebaner, 1994).

But a finite world cannot sustain infinite growth. One can therefore argue that probabilistic population dynamics show that all real populations will die out sooner or later. But before that happens there may be a long period of growth, or even – as recent research has shown – long periods of quasi-stationarity.

Indeed, consider a population where individual reproduction at any time is influenced by total population size, and assume that there is a *carrying capacity* K, a numerical value above which the population is subcritical and cannot sustain itself, whereas it is supercritical below K. Then, if starting small, it may die out directly, or else in time span of order log K, for large K, it will reach a band around the carrying capacity, where it will then stay during a period whose length is exponential in K, until it finally dies out (Jagers and Klebaner, 2011).

Stable Population Theory

In contrast to population size, the composition of growing populations, where individuals reproduce independently, tends to stabilize. The description of this composition, or rather the various stable compositions pertaining to different reproduction and survival laws, is the object of stable population theory.

The most well-known aspect of stable population composition is the stable age distribution, first described by Euler in 1760 and since then rediscovered repeatedly: if the Malthusian parameter is $\alpha > 0$ and all individuals have the same survival function ℓ, then the age of an individual sampled at random in an old population will have the density

$$\frac{e^{-\alpha a}\ell(a)}{\int_0^\infty e^{-au}\ell(a)\mathrm{d}u}$$

at age a, exactly as in deterministic theory. This is, of course, a law-of-large-numbers effect; we are considering ever-increasing populations.

If, as in the general setup mentioned above, there are several types of individuals, each with its own life span distribution, then the situation will be more complex. First of all, the type distribution will converge to a stable type law, determined by an eigen-measure property. Then the survival function l, above will have to be replaced by an average of all the different survival functions weighted by the stable type distribution.

But the stable composition describes many other aspects of a balanced growing population besides ages. For example, the probability of being firstborn can be calculated as well as other aspects of family structure. In modern evolutionary biology the genealogy of individuals and, say, the mutational history play an important role. In an old population this is described by a stable, typical ancestry, which can be used to determine time back to some event like divergence between species. In a strict sense, such results have yet been proven only for populations of independently reproducing individuals. Little is known about stabilization during the quasi-stationary stage in population size dependence.

Population Dynamics: Theory of Nonstable Populations

Cyrus CY Chu, Academia Sinica, Taipei, Taiwan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article introduces the demographic theory of nonstable populations. The analysis of population dynamics was originally a branch of mathematical biology but is also important for social demography because it provides elegant models for how populations ebb and flow.

Background

To introduce the theory of nonstable population dynamics, we start by presenting a Malthusian model studied by Lee (1974). Consider an overlapping-generation framework in which each individual lives one or two periods. The first period is childhood and the second is adulthood, and all surviving adults will be in the labor force. The Malthusian model can be characterized by the following two equations: $W_t = f(N_t)$, $b_t = g(W_t)$, where W_t is the wage rate (at time t), N is the size of the adult group, b is the crude birth rate, the $f(.)$ function characterizes the wage/employment relationship in the labor market, and the $g(.)$ function specifies the influence of the labor market reward on fertility.

Suppose the number of children born in period t is B_t, and the child survival rate is l, then $N_t = l \cdot B_{t-1}$. The above two equations can be combined in the following reduced form: $B_t = h(B_{t-1})$, where $h(B_t) = g(f(l \cdot B_{t-1})) \cdot l \cdot B_{t-1}$. The above expression is a recursive equation of B_t, from which the dynamic pattern can be analyzed, and the possible existence of cyclicity can be studied. Here, the Malthusian model is interpreted as a model of density dependency, where the density is characterized by the birth size of the previous period. It turns out that the Malthusian model described above may not converge to a 'dismal' steady state, as Malthus suggested. Mathematically, the B_t series may converge, diverge, or be cyclic, and the volatility of the birth series B_t crucially hinges on the feedback elasticity of $h(.)$ with respect to B_{t-1}. When this elasticity is sufficiently large, the B_t series can easily have cycles. This is the classical case of nonstable population. Modern versions of nonstable population will be discussed below, after we introduce the general population structure.

The General Population Structure

Let $N_t \equiv (N_{t,\ 1}, \ldots, N_{t,\ n})$ be an n-type population vector at period t, where $N_{t,\ i}$, $i = 1, \ldots, n$ indicates the size of type-i population at period t. The type here may refer to any criterion that is used to classify the population, such as age, sex, and occupation. A general formulation of population dynamics can be written as follows:

$$N_{t+1} = Q(N_t)N_t \qquad [1]$$

where $Q(N_t)$ is the transition matrix. The simplest case is when $Q(N_t) = Q$, a time-independent matrix. In this situation, the above equation reduces to a time-invariant Markov chain: $N_{t+1} = QN_t$. It is a well-known implication of the Frobenius–Perron theorem that if Q is positively regular, meaning that there is flexible cross-period mobility across types, then the population vector N_t will converge to a steady state, in which all elements of the N_t vector grow at the same exponential rate, thereby the population composition is also time invariant. It has been shown by Chu (1998) that, for most population models with time-independent Q, this positive regularity condition is likely to be satisfied, therefore any nonstable behavior of the population would appear only when $Q(N_t)$ is not a constant matrix, or equivalently when the relationship between N_{t+1} and N_t in eqn [1] has some nonlinearity. Below we will introduce several special cases of the generic setting in eqn [1], and discuss their empirical relevance. The reader can see that each model corresponds to a special interpretation of the generic setting in eqn [1].

Age-Structured Cycles

For demographers, the most familiar version of the dynamic models in eqn [1] is the Lotka–Leslie age-specific models, where the type criterion is age. Let $N_{t,\ i}$ be the number of population aged i at period t, B_{t-i} the birth size at period $t - i$, and l_i probability that a person can survive to age i, then the following relationship must hold: $N_{t,\ i} = B_{t-i} \cdot l_i$. The transformed dynamics in terms of B_t is the well-known Lotka's equation:

$$B(t) = \sum_i B_{t-i} \cdot l_i \cdot m_{t,i} = \sum_i B_{t-i} \cdot \phi_{t,i} \qquad [2]$$

where $m_{t,\ i}$ is the average number of births per surviving member aged i at period t, and $\phi_{t,\ i} \equiv l_i \cdot m_{t,\ i}$ is the net maternity function. Evidently, the Malthusian model presented in the previous section is a special case of eqn [2] with two age types. As we mentioned, when the fertility function $m_{t,\ i}$ is independent of t, then the process of B_t follows a time-invariant Markov chain, and the usual convergence result applies. But if $m(t, i)$ is time dependent, then cycles or more volatile behavior may appear. One typical case of such time dependency is when the age-specific fertility rates are functions of previous birth sizes $m_{t,\ i} = m_i \cdot (B_t)$, where $B_t \equiv (B_{t-1}, B_{t-2}, \ldots)$.

Suppose the birth series corresponding to eqn [2] has a steady state. Taking a Taylor expansion around this steady state, Lee (1974) showed that the volatility of the birth series characterized by eqn [2] hinges upon the elasticities of the net maternity function with respect to B_t. When previous birth

sizes are larger, usually the density pressure is larger. Intuitively, larger feedback elasticities imply that present reproduction would be more sensitive to previous birth shocks; hence the birth series would be more volatile. Easterlin (1961) argued that the baby-boom/baby-bust cycles observed in the United States are typical examples of a feedback cycle.

How large the feedback elasticities are is an empirical question. In order to estimate such elasticities, two models have been proposed: The first is to assume that $\phi_{t,\ i}$ is only a function of the cohort size aged i: $\phi_{t,\ i} = \phi_i \cdot (B_{t-i})$ and the second is to assume that $\phi_{t,\ i}$ is a function of the weighted average of birth sizes of different ages $\phi_{t,\ i} = \phi_i \cdot (\sum_j w_j \cdot B_{t-j})$. The former is referred to as the cohort model, and the latter as the period model. However, empirical evidence has so far failed to back up either of these two models in producing persistent birth cycles that fit all characteristics (such as amplitude and period). Moreover, even if there does exist a cyclic solution to eqn [2], the information concerning feedback elasticity is not sufficient for us to tell whether the cyclical solution in question is stable. Related analysis is rather technical, and the reader is referred to Tuljapurkar (1987) for details.

Predator–Prey Cycles

The predator–prey model describes a two-type population structure, where the types are prey and predator, respectively, referred to as type-1 and type-2. The simplest formulation of the predator–prey model is characterized by the following difference equations:

$$\begin{aligned} \Delta N_{t+1,1} &\equiv N_{t+1,1} - N_{t,1} \\ &= aN_{t,1} - bN_{t,1}N_{t,2} \\ \Delta N_{t+1,2} &\equiv N_{t+1,2} - N_{t,2} \\ &= -cN_{t,2} + dN_{t,1}N_{t,2}, \quad a,b,c,d > 0 \end{aligned} \qquad [3]$$

Equation [3] is obviously a special case of eqn [1]. The prey is considered the only food resource available to the predator. Thus, if $N_{t,\ 1} = 0$, the predator population decreases exponentially at the rate C. With the nonexistence of predators, the prey population grows exponentially at the rate a.

In the steady state of eqn [3], $\Delta N_{t,\ 1} = \Delta N_{t,\ 2} = 0$, there is only one nontrivial solution: $(N_1^*, N_2^*) = (c/d, a/b)$. Let the Jacobian matrix of eqn [3] around the nontrivial solution be denoted J. It turns out that the J matrix can be written as

$$J = \begin{pmatrix} a - bN_2^* & -bN_1^* \\ dN_2^* & -c + dN_1^* \end{pmatrix} = \begin{pmatrix} 0 & -bc/d \\ ad/b & 0 \end{pmatrix}$$

Hence, we have $|J| = ac > 0$ and the trace of J is zero.

Thus, we know that the eigenvalues of J are purely imaginary, meaning that besides the equilibrium point $(c/d, a/b)$ itself, the solution trajectories of eqn [3] are cyclic and nonstable. But it was also pointed out that when the predator–prey model embodies the concerns of diminishing or increasing returns, then the solution becomes locally stable or divergent.

Occupation–Switch Cycles

Based on stylized facts found in Chinese history, Chu and Lee (1994) proposed an occupation-specific population model, in which the population is separated into three types: peasants, soldiers, and bandits. Peasants grow crops and pay taxes, soldiers (rulers) collect taxes and hunt for bandits, and bandits rob food and clash with peasants and soldiers. It is assumed that soldiers are drafted by the government, and all other civilians can choose to become peasants or bandits. Their occupation choice is made depending on which occupation is expected to generate a higher utility. When the bandit/soldier ratio is relatively high, it is likely that the incumbent power regime will be overthrown by the bandit group, and the dynasty switches. It turns out that this pattern of population dynamics characterizes the dynamic evolution of dynasties in Chinese history, and the cycles were called dynastic cycles by historians.

There is a unique feature associated with the above-mentioned occupation-switching cycles. For most animals, it is believed that when density pressure occurs, the environment becomes less favorable, and the reproduction rate of animals is reduced. One might expect that rational human decisions may be able to weaken the outside density pressure through institutional and rational regulations. But the scenario of dynastic cycles seems to be a counterexample.

Human beings' occupational choice between peasants and bandits has a 'demonstration effect,' which tends to magnify the originally weak density pressure and 'destablize' the dynamics of the population compositional structure.

Laborer–Capitalist Cycles

The cyclical pattern of population composition mentioned above is not the only case we find in human societies. Some researchers have considered a neoclassical economic growth model, and focused on the two economic classes in the economy: the laborers and the capitalists. Let u_t be the income share attributed to labor, and v_t be the employment rate of labor. Under some reasonable assumptions, Goodwin (1967) has shown that the dynamics of u_t and v_t mimic that of eqn [3]. Thus, the conclusion that the capitalists' economy appears to be 'permanently oscillating' was reached. But just as the original predator–prey model is sensitive to variations in institutional specifications, Goodwin's model after some minor modification also generates qualitatively different results. Definite evidence of the nonstability of human population is yet to be found.

Human Development Cycles

The final population dynamics we discuss is related to the economic development process of human beings. The Neolithic Revolution about 10 000 years ago triggered the human society from hunter-gatherer to agricultural. The Industrial Revolution 250 years ago marked the beginning of the modern phase. In terms of population dynamics, we observe that in the agricultural epoch the population was dominated by the Malthusian rule with a stable population size and a constant per-capita income, whereas after we entered the industrial revolution we first experienced a demographic transition and then a near-replacement level population growth.

The demographic transition changes parents' choices from quantity to quality of children, and the increased level of child education leads to the growth of per capita income. In short, we have a subsistence level family income and stagnant population size 300 years ago, and a growing population size (estimated 9.3 billion by 2050) with drastically different income levels across countries. What is behind this big regime change of dynamics?

It was the contribution of Galor (2011) to have explained the above-mentioned regime change in a unified model. Among others, there are two factors that dominated the change of population dynamics. The first is the binding subsistence level of consumption in the Malthusian period, when parents cannot spare their resources to increase children's quality. The second is the improved life expectancy and the change of market/household comparative advantage, which facilitate women to adopt a quantity–quality trade-off. Countries in the modern world are therefore divided into pre-transition, transition-leaders and transition-followers. The first category has a fast population growth but yet a low income level, and the latter two categories have a stable population size and a growing income level.

Abstract

A population with an age distribution which remains constant over time is referred to as stable. A stable population of constant size is said to be stationary. These concepts are of considerable antiquity. Subject to age-specific mortality and fertility rates which remain unchanged over time a population will eventually develop a stable age distribution which depends on those mortality and fertility rates but is independent of the initial age distribution of the population. This result, due to Sharpe and Lotka (1911), caused renewed interest in stable populations among demographers, and the theory underlying it is outlined. Although demographers usually think of a stable population as one with an age distribution which is unchanging, such a definition is restrictive, because populations can also exhibit stability in respect of other characteristics as well as age and in more general situations. The discrete approach of Bernardelli, Leslie, and Lewis, which readily permits generalizations to a range of population stability situations is therefore described, as well as extensions covering migration, multiregional populations, populations studied by parity of woman, and membership of particular organizations. Applications are discussed only very briefly with cross-references to the relevant article. Limitations of the underlying models are also mentioned, again with a cross-reference.

A population with an age distribution which remains constant over time is referred to as 'stable.' A stable population of constant size is said to be 'stationary.' These concepts are of considerable antiquity. Euler, for example, knew in 1760 the stable age distribution a population needed to have if it were to have a given growth rate. Compilers of some of the early life tables such as Graunt in 1662 appear to have assumed populations which were stationary, and nineteenth-century actuaries certainly made use of the stationary population concept (King, 1902).

Subject to age-specific mortality and fertility rates which remain unchanged over time a population will eventually develop a stable age distribution which depends on those mortality and fertility rates but is independent of the initial age distribution of the population. This result, due to Sharpe and Lotka (1911) caused renewed interest in stable populations among demographers. Although demographers usually think of a stable population as one with an age distribution which is unchanging, such a definition is restrictive, because populations can also exhibit stability in respect of other characteristics as well as age and in more general situations.

The Population Model of Sharpe and Lotka

Sharpe and Lotka considered the male population alone and assumed that the growth of the female population would be such as to justify assumptions of constant age-specific fertility and mortality for the males. Subsequent writers have usually applied the model to the female component of the population because of its shorter reproductive age span and the fact that the number of females in the reproductive age range plays a more significant role in determining the number of births than the number of males (Pollard, 1973).

Applied to the female population, the model assumes $F(x, t)\,\mathrm{d}x$ females in the age range $(x, x + \mathrm{d}x)$ at time t and $B(t)\mathrm{d}t$ female births between times t and $t + \mathrm{d}t$. Then, if the average number of daughters born per female aged exactly x in time element $\mathrm{d}t$ is $\lambda(x)\mathrm{d}t$ and the probability that a female survives from age u to age $u + v$ is ${}_vp_u$, the following relationship is immediately apparent:

$$B(t) = \int_0^\infty F(x,t)\,\lambda(x)\mathrm{d}x \qquad [1]$$

Noting that those alive and aged x at time t, enumerated in $F(x, t)\,\mathrm{d}x$, must either have been born at time $t - x$ $(x < t)$ or else have been aged $x - t$ at time 0 $(x > t)$, eqn [1] may be rewritten as

$$B(t) = \int_0^t B(t-x)\,{}_xp_0\,\lambda(x)\mathrm{d}x + G(t) \qquad [2]$$

with

$$G(t) = \int_0^\infty F(x,0)\,{}_tp_x\,\lambda(x+t)\mathrm{d}x \qquad [3]$$

The solution to the integral equation (2) reveals that for large values of t, under quite general assumptions

$$B(t) \cong C\,e^{rt} \qquad [4]$$

where the constant r (the *intrinsic growth rate* of the population) is the unique real solution to the integral equation

$$\int_0^\infty e^{-rx}\;\;{}_xp_o\,\lambda(x)\mathrm{d}x = 1 \qquad [5]$$

and the constant C depends on the initial age distribution of the population as well as the age-specific mortality and fertility rates (Keyfitz, 1968; Pollard, 1973).

Since the females aged between x and $\mathbf{x} + \mathrm{d}x$ at time t are the survivors of those born x years earlier between times $t - x$ and $t - x + \mathrm{d}x$, it follows from eqn [4] that

$$F(x,t) \cong C\,e^{r(t-x)} \qquad {}_xp_o = \left(C\,e^{rt}\right)\left(e^{-rx}\;{}_xp_0\right) \qquad [6]$$

The first factor in the right-hand side of eqn [6] indicates that the population grows exponentially asymptotically at rate r, while the

second reveals that the age distribution is asymptotically independent of t. In other words, a *stable age distribution* is reached.

The Discrete Time Model of Bernardelli, Leslie, and Lewis

Whilst the continuous time model of Sharpe and Lotka is elegant and predicts a stable population asymptotically under conditions of constant age specific mortality and fertility, the discrete time formulation of Bernardelli (1941), Lewis (1942) and Leslie (1945), which makes similar assumptions, is more readily adapted to analyze stability in more complicated situations.

The number of females aged x last birthday at time t is represented by $n_{x,t}$. There is no migration, and no one can live beyond age k last birthday. The average number of daughters born to a female while she is aged x last birthday, those daughters surviving to be enumerated as being aged zero at the next point of time, is F_x, and the proportion of females aged x last birthday surviving to be aged $x+1$ last birthday a year later is P_x. Under these assumptions, the following matrix recurrence equation must apply to the numbers of females in successive years:

$$\begin{pmatrix} n_{0,\,t+1} \\ n_{1,\,t+1} \\ n_{2,\,t+1} \\ n_{3,\,t+1} \\ \cdots \\ n_{k,\,t+1} \end{pmatrix} = \begin{pmatrix} F_0F_1 & F_2\cdots & & F_{k-1}F_k \\ P_0 & & & \\ & P_1 & & \\ & & P_2 & \\ & & \ddots & \\ & & & P_{k-1} \end{pmatrix} \begin{pmatrix} n_{0,\,t} \\ n_{1,\,t} \\ n_{2,\,t} \\ n_{3,\,t} \\ \cdots \\ n_{k,\,t} \end{pmatrix} \qquad [7]$$

This equation may be written more concisely as

$$\mathbf{n}_{t+1} = \mathbf{A}\,\mathbf{n}_t \qquad [8]$$

so that

$$\mathbf{n}_t = \mathbf{A}^t\,\mathbf{n}_0 \qquad [9]$$

Under fairly general conditions, matrix $\mathbf{A}$ is positive regular, in which case it has a dominant eigenvalue α which is positive, of multiplicity one, and greater in absolute size than any other eigenvalue. It follows from eqn [9] therefore that for large t,

$$\mathbf{n} \cong C\,\alpha^t\,\mathbf{z} \qquad [10]$$

where C is a constant which depends on the initial age distribution of the population, and $\mathbf{z}$ is the column eigenvector corresponding to the eigenvalue α. If Π_s is written instead of the product $P_0P_1...P_S$, the elements of $\mathbf{z}$ are $\Pi_0\alpha^{-0}, \Pi_1\alpha^{-1}, ..., \Pi_k\alpha^{-k}$. It follows, therefore that the number of females aged x last birthday at time t is

$$n_{x,t} \cong \left(C\ \alpha^t\right)\ \left(\alpha^{-x}\ \Pi_x\right) \qquad [11]$$

This is the discrete analogue of the Sharpe and Lotka formula, eqn [6]. The second factor defines the asymptotic stable age distribution; the first shows the exponential growth of the population (Keyfitz, 1968; Pollard, 1973).

Stability with Migration

The most appropriate model for a population subject to significant migration must depend on the pattern that migration takes. In the case of a country accepting a constant number of immigrants each year with a constant age pattern, for example, the discrete time recurrence of eqn [8] needs to be modified as follows:

$$\mathbf{n}_{t+1}\ \ \mathbf{A}\,\mathbf{n}_t + \mathbf{b} \qquad [12]$$

where $\mathbf{b}$ is a constant vector of immigrants. Under this model, immigrants are assumed to adopt immediately the mortality and fertility patterns of their new homeland. Repeated application of eqn [12] for $t = 0, 1, 2, ...$ reveals that, provided the dominant eigenvalue of $\mathbf{A}$ is not equal to one,

$$\mathbf{n}_t \ = \ \mathbf{A}^t\,\mathbf{n}_0 + \left(\mathbf{I} - \mathbf{A}^t\right)\left(\mathbf{I} - \mathbf{A}\right)^{-1}\mathbf{b} \qquad [13]$$

If the rate of natural increase of the population is less than zero, α will be less than one, and for very large t

$$\mathbf{n}_t \ \cong\ \left(\mathbf{I} - \mathbf{A}\right)^{-1}\mathbf{b} \qquad [14]$$

The population will become stationary with its age structure determined by the ages of the immigrants (vector $\mathbf{b}$), as well as the mortality and fertility of the host country (matrix $\mathbf{A}$). Where the fertility of the host country is greater than replacement level, α will be greater than one, and the following asymptotic formula follows from eqn [13] for very large t:

$$\mathbf{n}_t \ \cong\ C'\ \alpha^t\,\mathbf{z} \qquad [15]$$

In this case, the population grows asymptotically with the same exponential growth rate as it did in the discrete non-immigration case of Section 2. The asymptotic stable age distribution (vector $\mathbf{z}$) is also the same. The constant C', however, is different, depending on the initial age structure, the vector of immigrants $\mathbf{b}$, and the mortality and fertility of the population.

In the pathological case where the levels of mortality and fertility in the population correspond exactly to replacement, α is equal to one, and a different algebraic approach is necessary to the solution of eqn [12], which yields, for very large t, the following asymptotic result:

$$\mathbf{n}_t \ \cong\ C''\ t\ \mathbf{z} \qquad [16]$$

The population grows linearly asymptotically and the asymptotic age distribution is the same as in the previous case. The constant C'' depends on the immigration vector, as well as the fertility and mortality rates of the population.

For a population experiencing net emigration with a proportion β_x of females aged x departing each year, the matrix model of Section 2 can be utilized with each of the P_x in matrix $\mathbf{A}$ replaced by P_x–β_x. The mathematical theory can then be applied in the same manner as before, and an asymptotic stable population emerges. The dominant eigenvalue and eigenvector will of course be different from those in Section 2. Depending on whether the dominant eigenvalue of the modified matrix $\mathbf{A}$ is less than, equal to, or greater than one, the population will ultimately decline, become stationary or grow in size.

The above models are only two of a very wide range of possible migration models appropriate in different circumstances. They demonstrate how the discrete time model of Section 2 may be readily modified to take account of migration and the fact that population stability will usually emerge in the presence of migration when the migration parameters, mortality, and fertility remain unchanged over time.

Generalizations

The discrete time models of the earlier sections are readily adapted to study populations partitioned according to other characteristics as well as age. Multiregional demography is the best known example (Rogers, 1966, 1975). Females of a population are characterized by age and geographical region in an extended column vector $\mathbf{n}_t$ of dimension mk, where k is the maximum age last birthday attainable and m is the number of regions in the country. As well as surviving and reproducing in the manner of Section 2 with rates that may differ from region to region, females can move from one region to another with transition rates which depend on the regions involved and may also depend on age. The matrix recurrence equation is again eqn [8], but with $\mathbf{n}_t$ of dimension mk and $\mathbf{A}$ of dimension $mk \times mk$. Conditions for a unique dominant eigenvector are readily determined, and asymptotic stability for the population by age and geographic region is predicted.

Another partition characteristic sometimes proposed is the *parity* of woman. Females at time t are enumerated in a vector $\mathbf{n}_t$ with elements $\{n_{x,y,t}\}$ which record the numbers aged x last birthday who already have y children. The only possible transitions for a female aged x and parity y remaining within the system are to age $x + 1$ and parity y or to age $x+ 1$ and parity $y + 1$ (ignoring the small possibility of multiple births). Where there is a change in parity, a new female will be introduced into the population aged 0 last birthday and parity 0 if the mother's change in parity corresponds to a female birth. Recurrence matrix $\mathbf{A}$ contains these transition rates. The fundamental recurrence equation is again eqn [8]. For all realistic populations, the enlarged matrix $\mathbf{A}$ will have a unique dominant eigenvector, and the population enumerated by age and parity will approach stability (Keyfitz, 1968).

The discrete-time models of Sections 2 and 3 have also been applied to workforce planning (Bartholomew, 1973; Pollard, 1967), membership of learned societies (where Fellows are elected on merit and there is a danger of the society becoming a rapidly aging institution), and membership of other groups including pension schemes (Sherris and Pollard, 1980). A learned society, for example, might have a policy of electing five new Fellows each year. The membership of the society at time t can be summarized by a vector $\mathbf{n}_t$ with elements $\{n_{x,t}\}$ representing the numbers at the various ages at that time. The number of new members (five) and their age distribution can be summarized in a vector $\mathbf{b}$. The transition rates in the recurrence matrix are simply the proportions $\{P_x\}$ surviving from age x last birthday to age $x + 1$ last birthday a year later, for all relevant ages. Assuming that the ages are listed in their natural increasing order, the transition matrix $\mathbf{A}$ is particularly simple in this case: all its elements are zero, except those immediately below the main diagonal which comprise the survival proportions $\{P_x\}$. With $\mathbf{n}_t$, $\mathbf{b}$, and $\mathbf{A}$ defined in this manner, the recurrence equation for the society is eqn [12]. All the eigenvalues of $\mathbf{A}$ are zero, and for t greater than the number of ages involved, $\mathbf{A}^t = \mathbf{O}$. The society will approach a stationary state given by eqn [14].

All such linear models with realistic assumptions concerning transition between states, entry and reproduction can be shown to predict stable populations asymptotically.

Applications

No observed population experiences constant levels of mortality and fertility. Nevertheless the concept of a stable population finds frequent application. Keyfitz's elegant formula for the effect of population momentum (*see* Population Dynamics: Momentum of Population Growth) assumes that the population is stable immediately prior to fertility falling to replacement level. Yet the formula works remarkably well for observed populations which are not stable. Stable population theory may be helpful in deducing results in respect of populations with unreliable and/or limited demographic data. Equation (4), for example, can be used to infer an approximate value for the crude birth rate of a population where contraception is not widely practiced, using only a reliable census of the population and a more or less appropriate life table (Bourgeois-Pichat, 1957). Many of the applications of model life tables rely on stable population theory (*see* Population Dynamics: Classical Applications of Stable Population Theory).

Limitations

The discrete time model of Bernardelli, Leslie, and Lewis, like the continuous (female) formulation of Sharpe and Lotka, assumes that the development of the male component of the population is such as to justify the assumption of unchanging female age-specific mortality and fertility. Linear models which include the male component of the population alongside the females have also been proposed, and mathematical analysis analogous to that presented in Section 2 predicts a stable age–gender composition for the whole population. Nonlinear models have also been proposed to accommodate the 'two-sex problem' (*see* Population Dynamics: Two-Sex Demographic Models). Many of these nonlinear models would also seem to predict populations which are asymptotically stable under conditions of unchanging rates of mortality, fertility and nuptiality.

For many developing countries, for which stable population theory had been an extremely helpful tool, mortality began to decline in the second half of the twentieth century, but fertility remained essentially unchanged from previous levels. To accommodate the improvements in mortality, the concept of a quasi-stable population was introduced: one with improving mortality but constant fertility (Coale, 1963).

Population Dynamics: Two-Sex Demographic Models

Robert Schoen, Pennsylvania State University, University Park, PA, USA

This article is a replacement of the previous edition article by R.A. Pollak, volume 17, pp. 11773–11777, © 2001, Elsevier Ltd.

Abstract

Demographic models of marriage and fertility that incorporate the behavior of both males and females encounter the so-called 'two-sex problem.' That problem arises because observed one-sex male and female rates of marriage and birth are influenced by the total age–sex composition. The leading two-sex solution that has been advanced is the harmonic mean approach, which assumes that the sum of male and female marriage or birth rates is independent of such compositional effects. Although other serious alternatives have been proposed, the harmonic mean approach is based on the most plausible demographic foundation.

The marriage squeeze is the best known manifestation of two-sex population dynamics. Using the harmonic mean approach, analyses indicate that over the past 50 years marriage squeezes have had significant impacts on the timing of marriage. Nonetheless, marriage squeezes have had less influence on the probability of ever marrying, and are unlikely to have played a major role in large-scale social change.

Human populations have two sexes, males and females, but demographic models generally depict only one sex. The major reason is the so-called 'two-sex problem,' the fact that conventional marriage and birth rates are shaped by the composition of the entire population.

Here we examine the nature of the two-sex problem, alternative approaches that have been proposed to deal with it, and touch on some demographic models that incorporate the experience of both sexes. Then we consider the 'marriage squeeze' and the 'birth squeeze,' real world manifestations of two-sex demography, and examine their impact on population dynamics.

The Two-Sex Problem

To begin, let us consider a hypothetical population of 100 males and 100 females, which experiences 10 marriages during the course of a year. Conventional one-sex incidence/exposure rates of marriage are given by the number of marriages divided by the population at risk. Here, the male marriage rate, W_m, is $10/100 = 0.1$. That is identical to the female marriage rate, W_f. If the underlying propensity to marry is unchanged and the number of males and females continues to be equal, rates of 0.1 will continue to yield the annual number of marriages in the population.

Now assume that the propensity to marry and the size of the female population remain unchanged, but the size of the male population increases to 200. Applying the male rate to the male population gives 20 marriages, while applying the female rate to the female population yields 10 marriages. Given the traditional definition of marriage as involving one male and one female, it is clear that both the male and female rates cannot persist when relative population size changes. In a real population, we would expect the number of observed marriages to increase, but not to double, because the number of females did not double. Hence the male marriage rate would fall below 0.1 while the female marriage rate would rise above 0.1. The two-sex problem is to determine exactly how male and female marriage rates would change. While here we only consider traditional marriage, a 'two-sex' problem would still exist if partnerships were formed independent of gender, as long as propensities to partner varied by age or some other demographic characteristic.

The Harmonic Mean Solution

Schoen (1981) argued that if there were no change in the propensity to marry, the rise in the marriage rate for one sex would exactly offset the fall in the marriage rate for the other sex, leaving the sum of the male and female rates constant. That sum of male and female rates, termed the 'magnitude of marriage attraction,' would reflect the underlying propensity to marry between males and females, and would be independent of population composition. Magnitudes of marriage attraction, like rates, could be made specific to age and other characteristics of the men and women marrying. If two populations have the same magnitudes of marriage attraction, then, in every case, the sum of the characteristic-specific male and female marriage rates would be equal, even though the corresponding male and female rates might differ.

The above approach is a harmonic mean solution because the magnitude of marriage attraction, as the sum of male and female rates, equals the number of marriages divided by half the harmonic mean of the number of males and females. The magnitude of marriage attraction is zero if either the number of males or females is zero, and if one sex is large relative to the other, is proportional to the number in the less numerous sex. If the number in both sexes increases by factor f, then the number of marriages increases by factor f. The denominator of the magnitude of marriage attraction can also be interpreted as the total number of male–female pairs divided by the sum of the male and female populations. Hence the 'two-sex population' denominator is the average number of possible pairs per person.

An important property of a two-sex solution is sensitivity to the age–sex composition of the entire 'marriage market,' i.e., all persons eligible to marry. For example, the chance that a 25 year old man will marry a 24 year old woman should be influenced by competition from the number of men aged 24 and women aged 23, and indeed by the number of eligible men and women at all ages. It is not obvious that the harmonic mean approach, which determines the magnitude of marriage attraction from just the number of men aged 25 and women aged 24, does so. Yet, the harmonic mean approach is sensitive to the marriage market because of the intimate relationship between population stocks (numbers of persons) and flows (here, marriages).

Consider two points. First, the number of persons in the (midyear) population eligible to marry and the number of observed marriages reflect outcomes from the competitive environment of the marriage market. Second, recall that rates are based on the experience of a given year. Now assume that we are at the beginning of a year of observation and know the array of magnitudes of marriage attraction and the initial number of unmarried persons by age and sex. To calculate the number of marriages by age and sex, we need the midyear, not beginning of the year, populations. Those midyear populations are affected by the marriages that occur during the first half of the year, thus the size and composition of the midyear populations bears the imprint of the competitive context of the marriage market.

Because of its desirable properties, the harmonic mean approach is generally accepted as 'a' solution to the two-sex problem. However, there is no consensus as to 'the' solution, and a number of other serious approaches have been advanced.

Alternative Two-Sex Solutions

Schoen (1988: Chapter 6) reviewed a number of solutions to the two-sex problem that have been advanced. Here, we focus on 4 approaches: (1) other simple means or combinations of rates; (2) iterative proportional fitting; (3) panmictic circles; and (4) the birth matrix-mating rule approach. Since the essence of the two-sex problem is how population composition impacts male and female rates, methods based only on relative numbers of males and females are not explored.

Other Simple Means or Combinations of Rates

The simple arithmetic mean, i.e., half the sum of the male and female rates, is an obvious possibility. However, it has received little attention because it yields marriages even when there are no persons of one sex.

The geometric mean, i.e., the square root of the product of male and female rates, is a simple average that avoids the problem of marriages when there are no persons of one sex. Goodman (1967) discussed a geometric mean variant where the two sexes are given unequal weight, that is where the male rate would be raised to the power α ($0 \leq \alpha \leq 1$) and the female rate would be raised to the power $(1 - \alpha)$. Parameter α would indicate the 'dominance' of one sex.

Rather than averaging male and female rates, one could simply take the minimum of the two rates. That 'minimum' approach avoids the problem of marriages in the absence of one sex, and has been incorporated into more sophisticated models.

Iterative Proportional Fitting

McFarland (1975) applied a variation of the statistical technique of iterative proportional fitting (IPF), also known as the Deming-Stephan procedure or biproportional adjustment. Essentially, IPF begins by creating a marriage array, i.e., a cross-tabulation of marriages by age of bride and age of groom. The rows of the array contain elements showing the numbers of marriages for a given age of the bride and each age of the groom, plus an additional element equal to the total unmarried female population that age minus the total number of women marrying at that age. The columns contain elements showing similar numbers of marriages for a given age of the groom, plus an additional element equal to the total unmarried male population at that age minus the number of men marrying at that age. The row and column sums of the array, i.e., the marginals, are thus the total marriage eligible populations at each age. To apply IPF, change the marginals to the values for the population whose marriages are to be found. Then repetitively, or iteratively, multiply each row of the array by a factor that will yield that row's marginal. Next multiply each column of the array by a factor that will yield that column's marginal. Continue until no further row or column adjustments are needed. The process will always converge to a unique solution, and the resulting array will give the desired distribution of marriages by age and sex. If only one marriage age is involved, IPF is identical to the geometric mean approach. IPF is quite flexible, preserves the cross-product ratios of the original array, and is a maximum entropy (or minimum information) solution.

Marriage within Panmictic Circles

Henry (1972) viewed the marriage process as one involving men and women meeting and marrying within overlapping 'circles,' or large social groupings, within which marriage is 'panmictic' in the sense that age does not influence partner choice. Henry set forth a process for dividing male and female population distributions into a series of such circles, arguing that a maximum of six circles would be sufficient to characterize national level data. Within circles, male and female age-circle-specific marriage rates can be calculated, and those rates applied to other populations that have been decomposed into panmictic circles. The male rate yields one number of marriages and the female rate yields another, with the minimum number used. The procedure is not readily visualized, but seems to respond to competition in the marriage market.

The Birth Matrix-Mating Rule Model

Pollak (1990), building on the work of Feeney (1972), advanced the birth matrix-mating rule (BMMR) model consisting of three fundamental components. The first component is a birth matrix, indicating the number of children born to each possible union type (e.g., males age y and females age x). The second is a mating rule, which gives the number of unions

of each kind from the number of males and females in each category. The third has the applicable male and female age-specific death rates.

Under a number of possible mating rules, the BMMR model provides the long term male and female age distributions and the age pattern of marriage. The mating rule used must satisfy two fairly weak conditions: it must not yield negative numbers and it cannot yield more male (female) unions in an age category than there are males (females) in that category. The model yields a unique result if an increase in the number of persons in any age category does not decrease the number of births.

The BMMR model offers a framework for two-sex model solutions, rather than a specific solution. The harmonic mean, geometric mean, and IPF approaches, among others, can provide satisfactory rules whose demographic implications can be found using the BMMR approach.

Evaluating Alternative Two-Sex Solutions

Demography is empirically oriented, so it is logical to try and evaluate alternative approaches by applying them to actual data. The problem is that the standard for comparison – the correct result – is unknown. The most promising approach is to compare the same population over time, but that still requires the rather strong assumption that all of the propensities have remained constant. Schoen (1981) made such comparisons for Sweden, using single year of age male and female population and marriage data for the years 1961, 1962, 1963, and 1964. The harmonic mean, iterative adjustment, and panmictic circles approaches were each applied to the data, using 1961 data to predict 1962 marriages, 1962 data to predict 1963 marriages, and 1963 data to predict 1964 marriages. None of the three approaches performed well. All of them tended to be off in the same direction, but in an inconsistent and erratic fashion. A recourse to data thus seems unlikely to provide a useful evaluation of alternative two-sex solutions.

Another approach has been to posit a set axioms or conditions that a satisfactory method must satisfy, e.g., those set forth by Parlett (1972) or those required by the BMMR model. That approach has not worked well either, as no set of axioms has been generally accepted, and the leading two-sex solutions satisfy virtually all of the required properties that have been proposed.

There appears to be no alternative to evaluating two-sex solutions on theoretical or conceptual criteria. To be considered an acceptable solution, a two-sex approach should not only yield reasonable results empirically, but be based on a plausible, demographically meaningful rationale. In that respect, the harmonic mean emerges as the most satisfactory approach. No clear explanation has been offered for why the cross-product ratios of a marriage matrix should be preserved, why marriage should be independent of age within a few large 'circles,' or why the geometric mean captures the interaction between the sexes. In contrast, the harmonic mean method is based on magnitudes of attraction that reflect the marginal change in the number of marriages (or births) given a marginal change in the number of couples, and that imply a two-sex population at risk equal to the average number of pairs per person.

Two-Sex Demographic Models

Traditional one-sex demographic models can be extended to incorporate two-sex marriage or two-sex fertility. Along the three dimensions of single state/multistate, stationary/stable, and one-sex/two-sex, Schoen (1988: p. 120) identified six distinct two-sex nuptiality models and two two-sex fertility models.

The conventional, one-sex life table follows a cohort, or closed group of persons, over time, often recognizing more than one cause of decrement (loss) from the cohort. In particular, a one-sex nuptiality–mortality life table follows single person from birth to decrement from either first marriage or death, based on rates from a source population. The corresponding two-sex nuptiality–mortality life table follows a male cohort and a female cohort from birth to first marriage or death. The source population provides the one-sex male and female rates as well as the two-sex magnitudes of marriage attraction.

The classical one-sex stable population depicts the implications of a set of male or, more usually, female age-specific birth and death rates, showing the long term exponential population growth and constant age composition that those rates imply. Similarly, a two-sex (fertility) stable population shows the implications of the source population's male and female death rates and magnitudes of fertility attraction, i.e., sums of male and female age-specific birth rates.

A number of two-sex life table and stable population models have been constructed and analyzed, though such analyses are still infrequent. Two-sex modeling demands extensive input data, and is hampered by a lack of consensus on the appropriate two-sex methodology.

Manifestations of Two-Sex Behavior

Two-sex population dynamics, or the interaction between the sexes with regard to marriage and birth, is important to study because it influences marriage and fertility behavior. An imbalance between the number of men and women at the prime ages of marriage (or reproduction) alters the marriage (or fertility) rates of both sexes, and the effect can be substantial. A gender imbalance at the marriage ages produces what has been termed a 'marriage squeeze.' The analogous phenomenon, a 'birth squeeze,' can arise with respect to fertility. We examine each in turn, using measures based on the harmonic mean approach.

The Marriage Squeeze

Marriage squeezes typically arise when the number of births is rapidly rising (or falling). In most populations, men marry women several years younger than themselves. Thus when the number of births is increasing, men are looking for partners born in larger cohorts while women are looking for partners born in smaller cohorts. The result is a marriage squeeze disadvantaging females. If the number of births is falling, then the same process yields a marriage squeeze disadvantaging males.

Some observers have theorized that the marriage squeeze played a key role in social change during the twentieth century. Heer and Grossbard-Shechtman (1981) argued that a marriage squeeze against females reduced the proportion of US women

who married during the 1960s, changing the 'terms of trade' between men and women and increasing women's labor force participation. Davis and van den Oever (1982) interpreted the feminist movement as a response to lower fertility, less marriage, and the marriage squeeze. Guttentag and Secord (1983) argued that whenever there are *Too Many Women* (the title of their book), as in the United States during the 1960s and 1970s, marriage and family life are devalued and sexual libertarianism prevailed. Such claims by serious researchers deserve careful consideration and analysis.

Because two-sex dynamics change one-sex rates, we want a marriage squeeze measure that reflects how compositional changes have influenced male and female behavior. One such measure is marriage squeeze index S (cf Schoen, 1988). Index S is the male life table number of male marriages, minus the female life table number of female marriages, divided by the total number of marriages in the two-sex nuptiality life table. If $S > 0$, there is a marriage squeeze against females, if $S < 0$, there is a marriage squeeze against males, and if $S = 0$, there is no marriage squeeze at all. The larger the magnitude of S, the greater the squeeze. For example, if there were 98 marriages in a male life table, 92 marriages in a female life table, and 96 marriages in a two-sex table, then $S = 6/96 = 0.0625$.

Schoen (1983) looked at index S in 25 countries during the period 1966–75, using data from the 1976 United Nations Demographic Yearbook. The largest marriage squeezes were found in Jordan 1970 ($S = 0.14$) and Costa Rica 1973 ($S = 0.12$). More developed countries had S values that were either small or negative, the most negative being Sweden 1975 ($S = -0.04$). Schoen and Baj (1985) examined trends in index S in five Western countries (Belgium, England and Wales, Sweden, Switzerland, and the United States) during the period 1910–75. In the post–World War II period, S values were small, though Switzerland's was about 0.03 and Sweden's became negative. However, in the 1910s and 1920s, England and Wales, Sweden, and Switzerland had S values of 0.125 or above.

Schoen (1983) also looked at the marriage squeeze and its implications for the United States during the period 1950–90, assuming that 1970 magnitudes of marriage attraction applied over that period. Index S was always quite small, varying between 0.0013 and 0.0073, showing a slight marriage squeeze against females. Closer examination, however, revealed significant changes in the distribution of male and female marriages. The male mean age at marriage varied by 0.52 years, the female mean age at marriage by 0.62 years, and the mean difference between partner marriage ages fluctuated between 1.84 and 2.99 years. The variance of the distribution of both male and female ages at marriage also changed substantially.

In sum, studies suggest that marriage squeezes of some magnitude do characterize the contemporary world. While marriage squeeze effects on the proportion ever marrying appear modest, at least in Western countries, they have exerted substantial influence on the timing and distribution of marriages, including the age difference between spouses. Still, the evidence falls short of supporting the marriage squeeze as a cause of large-scale social change. In the 1910s and 1920s, sizable marriage squeezes in the West passed with little comment, and most social change since the 1960s, when the marriage squeeze has been small, seems attributable to more fundamental social and economic transformations.

The Birth Squeeze

The same demographic dynamic that produces marriage squeezes produces birth squeezes, even when marriage is not a necessary societal prelude to fertility.

The standard measure of fertility is the total fertility rate (TFR_f), the sum of age specific female birth rates over the female reproductive age span. The TFR_f can be interpreted as the average number of children a woman would bear in her lifetime in the absence of mortality. Fertility analysis has traditionally emphasized female birth rates because of the narrower female reproductive age span and the fact that data on fathers are often incomplete. Though less frequently calculated, TFR_m, the male total fertility rate, is the sum of male fertility rates over the male life course.

The approach expressed here, i.e., that two-sex dynamics affect one-sex rates, but that the sum of male and female rates is composition independent, applies to fertility as well as marriage. Following Schoen (1985), define the two-sex total fertility rate, TFR2, as one-half the sum of TFR_m and TFR_f. Paralleling index S, birth squeeze index U can be defined as $(TFR_m - TFR_f)/TFR2$. When $U > 0$, there is a birth squeeze against females, when $U < 0$, there is a birth squeeze against males, and when $U = 0$, there is no birth squeeze.

Schoen (1985) examined index U for 22 countries during the 1963–74 period, using data from the United Nations Demographic Yearbooks. Developed countries in the sample typically had small or negative values of U. For the United States 1970, U was 0.12. Four countries, Phillipines 1973, Jordan 1974, Tunisia 1971, and Puerto Rico 1970, had U values over 0.25. The Phillipines 1973, where U was 0.30, was the highest, having a TFR_m of 4.6 and a TFR_f of 3.4.

Since population growth is associated with birth squeezes against females, it is not surprising that growing populations have sizable values of U. Less obviously, when $TFR2 > TFR_f$, an argument can be made that the conventional TFR is understating the population's actual propensity for fertility.

Conclusion

Conventional one-sex demographic rates are unable to capture the dynamics underlying two-sex marriage and fertility behavior, or to model such demographic phenomena as the marriage squeeze. The harmonic mean approach, the leading two-sex solution to date, affords an opportunity for such analyses. The results have provided strong evidence that marriage squeezes have had considerable influence on the timing and pattern of marriage, but little support for a belief that marriage squeezes have caused major societal change.

Population Forecasts

Juha M Alho, University of Helsinki, Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Population forecasts are used to summarize existing knowledge of population change to help decision makers. Since the 1920s, the previously favored curve fitting methods were replaced by the cohort component method that adds age and sex details. This requires separate forecasting of age-specific fertility, mortality, and migration. A defect in the classical cohort component methods is that they fail to convey to the forecast users an impression of the statistical uncertainty of the forecast in an understandable way. In particular, the high–low variants that have often been used suffer from logical defects. Probabilistic approaches have been developed for the task. Due to the availability of fast computing, simulation can be used to generate a population of sample paths for the population by age and sex, for the future years of interest. The sample paths provide a numerical approximation to the predictive distribution of the future population. Such results can be used, for example, in macroeconomic analyses of aging, sustainability of public finances, or planning of health care or education.

Population forecasts are used to summarize existing knowledge of population change to help decision makers. Most methods of forecasting that are currently used by official statistical agencies were developed during 1920s to 1940s. Previously, the calculations concerning future population usually involved the fitting of mathematical curves (exponential or logistic, for example) to the trajectory of population size. The so-called cohort component method added age and sex detail. It can give important insight into how current vital rates (fertility, mortality, and migration) and current age distribution combine into the observed growth rate. Nevertheless, to improve overall accuracy, good forecasts of the age-specific vital rates are needed. Most population forecasts are purely demographic, that is, they do not take explicitly into account the social and economic factors that influence the vital rates. This is because such factors are often harder to predict than the demographic phenomena themselves. Similarly, the possibility that a forecast might become a self-fulfilling or self-negating prophecy is usually ignored. A defect in the classical cohort component methods is that they fail to convey to the forecast users an impression of the statistical uncertainty of the forecast in an understandable way. Probabilistic approaches have been developed for the task. Due to the availability of fast computing, simulation can be used to generate a population of sample paths for the population by age and sex, for the future years of interest. The sample paths provide a numerical approximation to the predictive distribution of the future population.

Population forecasts summarize existing knowledge about the change in the size and structure of populations. They support decision making by providing broad perspectives for future development, for problems related to aging, pension, health systems, etc. Although simple deterministic forecasts can provide us with important insights, policy design and risk management in the context of such macroeconomic issues require that uncertainty be realistically quantified. Although the fundamental reasons for the unpredictability of demographic processes are only poorly understood, the development of new statistical models and the availability of fast computing allow a realistic description of forecast uncertainty in terms that are understandable to nonspecialist users.

Development of the Cohort-Component Method

Curve Fitting Approach

Early calculations concerning the renewal of populations were based on simple mathematical models. Suppose $V(t)$ is the total population at time t. If the rate of growth is constant, or $V'(t)/V(t) = r$, then the population grows exponentially, $V(t) = V(0)e^{rt}$, from the starting, or *jump-off* population, $V(0)$. If the rate of growth decreases with increasing population according to $V'(t)/V(t) = r(M - V(t))/M$, where M is a limiting population size, then the growth is *logistic*: $V(t) = Me^{rt}/(1 + e^{rt})$. A discrete time version of the exponential model was used, for example, by T. Malthus in his *Essay on the Principle of Population* in 1798. The logistic model was introduced by F. Verhulst in 1838.

Such models were widely criticized for the following reasons: (1) they do not give age detail; (2) they do not allow a change from increase to decrease; (3) they are too mechanistic for human populations; (4) even though the exponential and logistic models are empirically indistinguishable when $V(t)$ is small relative to M, they give completely different long-term forecasts.

Incorporation of Age Structure

Methods for describing age-structured populations were developed around the turn of the nineteenth century in many countries; first in England by E. Cannan in 1895. By the end of the 1920s, forecasts by age and sex had also been made for the Soviet Union, The Netherlands, Sweden, Italy, Germany, France, and the United States (de Gans, 1999).

Suppose $V(x, t)$ is the size of the female population at age x at the beginning of year t. Then, for ages $x > 0$, we have the bookkeeping equation $V(x + 1, t + 1) = V(x, t)\, p(x, t) + N(x + 1, t + 1)$, where $p(x, t)$ is the probability of surviving from age x to age $x + 1$ during year t, and $N(x + 1, t + 1)$ is the net number of migrants during year t who are at age $x + 1$ at the beginning of year $t + 1$. For age $x = 0$ we have, $V(0, t + 1) = \sum_x f(x, t)V(x, t) + N(0, t + 1)$, where the summation is over the childbearing ages (often $x = 15, \ldots, 49$), and $f(x, t)$ is the expected number of children at age 0 at the

beginning of year $t + 1$ that were borne by women at age x during year t. Corresponding formulas can be written for the male population, and they can be extended to comprise several regions. This system of calculation is called the *cohort-component* (c-c) method.

Advantages of the Cohort-Component Method

The c-c method can be viewed as a response to the criticisms of the Section Curve Fitting Approach in the following sense: (1) Since the c-c method treats the population by age groups, it provides direct estimates of the future population by age and sex. That this is useful for the planning of housing, schools, hospitals, etc., was understood from the beginning. (2) The c-c method makes no assumption about the growth rate. It shows that, other things being equal, the growth rate increases with the proportion of women of childbearing ages. In 1925, L. Dublin and A. Lotka introduced the concept of intrinsic rate of growth. For a closed population with unchanging fertility and mortality, it gives the asymptotic rate of growth. As such it provides important insight into the renewal of populations that cannot be detected from current growth rates. Many of the early cohort-component forecasts assumed unchanging fertility and mortality, and no migration, and showed that the size of the childbearing population, and with it the total population, would cease to grow, even though the populations had been growing fast during the early 1900s. This contradicted the forecasts by exponential and logistic models. (3) The reason why the c-c forecasts are less mechanistic than those based on exponential or logistic curves is that they utilize the available information or assumptions about the change of the *vital rates* (of fertility, mortality, and migration). The forecasters of the 1920s knew that fertility and mortality had been declining for decades. How far down would they go and how fast? Examples from other countries or from privileged social groups were used as leading indicators for future mortality. The spreading of the urban lifestyle was seen to lead to a decrease in fertility. Opinion surveys were developed around 1940 to collect data on desired family size (Whelpton et al., 1947). (4) The early forecasters knew that the exponential, logistic, and other curves often gave similar fits to past data, but led to very different forecasts. Since statistical *model choice* depended on judgment but had a drastic effect on the results, why could one not use judgment in other ways as well? The solution by Whelpton to this problem was to set up targets for future vital rates, and to connect the most recently observed rates to the targets by suitable mathematical curves. Dutch forecasters had also used similar methods. This practice has been widely followed, and most national population forecasts use judgmental methods for specifying future vital rates, often via explicit targets (Andrews and Beekman, 1987).

Although the c-c method was an improvement over the curve fitting methods, it was soon understood that it was really a bookkeeping framework, and without an accurate specification of the future change in the vital rates improvements in forecast, accuracy would not materialize.

As an example, we may consider a forecast of Sweden that was crafted by S. Wicksell in 1926. The forecast had 1920 as the jump-off year with a population of 5.90 million. It had five fertility variants. For 1940 the most likely forecast was 6.53 million inhabitants. The high forecast was 6.87 million and the low forecast was 6.28 million. The actual population size was 6.37 million, hence the error was 2.5%. For 1970 the most likely value was given as 6.67 million and the high–low interval was [6.26, 8.44] million. The true value was 8.08 million so the error was −17.5%, but the high–low interval still gave a realistic indication of the uncertainty of the forecast. This is in contrast to many official forecasts, whose high–low intervals have been so narrow that the actual population count has escaped from the interval in a decade, if not sooner.

Foundational Aspects in the Forecasting of the Vital Rates

Most national forecasts of the vital rates are purely demographic, that is, they do not explicitly incorporate social or economic factors. Only rarely do they take into account the fact that the forecast itself might influence the future development. Partly because of these factors, and partly because of the poor accuracy of past forecasts, there has been a lengthy debate about whether the results of the calculations would be better interpreted as mere 'projections' rather than 'forecasts.'

The Difficulty with Explanatory Models

Refinement in demographic analysis often refers to the partitioning of the population at risk into more meaningful subgroups. For example, instead of relating births and deaths to the total population (which gives the crude birth and death rates), one may relate births to age of mother and consider deaths by age and sex (which gives the age-specific fertility and mortality rates) (*see* Demographic Measurement: General Issues and Measures of Fertility; Demographic Measurement: Nuptiality, Mortality, Migration, and Growth; Demographic Techniques: Lexis Diagram). The use of crude rates in exponential or logistic models can imply growth forever, whereas the use of the age-specific rates in a c-c model may imply a future decrease of the same population.

The analysis can be further refined. Age-specific rates may be analyzed for birth cohorts and by parity; marital and nonmarital fertility may be considered separately; or one may consider fertility by race, for example. Empirical evidence of whether this improves accuracy is mixed.

However, the more fundamental social or economic factors that determine the fertility, mortality, and migration of population subgroups are rarely used explicitly in forecasting. This is because future changes in such factors can be harder to forecast than the vital processes themselves. Keyfitz (1982) reviews many of the difficulties.

One attempt at solving the problem has been *conditioning*. By making detailed assumptions about the future course of relevant social and economic factors, forecasters have sought to formulate conditional forecasts, or *scenarios*, in which the evolution of the vital processes would follow assumed relationships with their determinants. A drawback of such an approach is that the manner in which the conditioning is done can have a major effect on the results. A *sensitivity analysis* that systematically varies some of the assumptions may then be helpful.

Self-Fulfilling or Self-Negating Prophecies

In some countries such as Germany and France the early population forecasts were motivated by the fear of population decline and loss of political power. In the Netherlands overpopulation was the concern. In both cases the forecasts were seen as a means of influencing social policies (de Gans, 1999). Inasmuch as the forecasts were influential, they were self-negating.

In other cases such as regional forecasting, a forecast of population growth may cause the local society to develop the infrastructure of an area to allow for future growth. The favorable circumstances created may then turn the forecast into a self-fulfilling prophecy.

Although examples of both types of 'prophecies' exist, it has been difficult to demonstrate the causality in a historical context. Deliberate government attempts at lowering (or increasing) fertility, or lowering mortality, have seldom had long-lasting effects that could be attributed to the policies as opposed to other concurrent factors.

Forecast Errors and the Debate on Terminology

From the very start, forecasters have been aware that the future vital rates cannot be known with certainty. Evaluations of past forecasts have vividly demonstrated the unpredictability of demographic change. For example, the post-World War II baby boom was missed by all forecasters, in Europe and the United States. After the baby boom fertility, forecasts have tended to be too high. Notably, the decline of fertility by one-third in Central and Southern Europe in the 1980s, came as a surprise.

Mortality has declined faster than anticipated. In his 1926 forecast Wicksell expected that Swedish life expectancy would increase from 58 years to an eventual maximum of 69.5 by 2025, but in 2010 life expectancy was already 83.5 for women and 79.5 for men. Comparable errors occurred in many other countries. As another example, the purported maximal life spans for humans have often been exceeded by the time they have been published (Oeppen and Vaupel, 2002).

To safeguard their reputation some forecasters have occasionally tried to communicate the uncertainty by using the terms 'projection' or 'illustrative projection' for the results of their calculations. This is a reasonable practice, for example, if the calculation consists of a c-c forecast with constant vital rates, when no one expects the rates to remain constant. However, as pointed out by H. Dorn in 1950, the producers of official forecasts typically publish calculations that are based on what they consider as the most likely future vital rates, and users also interpret the results in that way. Indeed, we may define a calculation based on what is regarded as the most likely assumptions as a *forecast*.

Statistical Uncertainty in Forecasting

Although probabilistic terminology is used in many branches of demography (e.g., probability of death in life tables) (*see* Life Table), and experience has shown that forecasts of the future population have been highly uncertain, the forecasting models considered so far have all been deterministic. The recognition of the uncertainties in probabilistic terms opens up new possibilities to enhance the usability of the forecasts.

Uncertainty in the Events and in the Rates

Consider a childbearing population of size V. Suppose the number of births during a year is B. We can think of B as a sum of V random experiments with an average probability f of a birth. The expected number of births is $E = fV$. Based on a Poisson approximation one can estimate that in a sequence of B values the relative variability (coefficient of variation) is $E^{-1/2}$. In a small regional population we may have $E = 100$, for example. Then, the births vary by about 10% each year due to random variation alone. However, if $E = 10\,000$, they only vary by about 1%, and if $E = 1\,000\,000$ they vary by 0.1% each year. It was pointed out by J. Pollard in 1973 that much larger relative variations are observed in the numbers of births in different countries, so this type of Poisson variation does not account for the variability of the observed birth processes.

The situation changes if we allow f to change from year to year with a coefficient of variation c (or by $100c$ percent). Then the relative variation is at least c, irrespective of the expectation E. The conclusion is that for forecasting large populations, the uncertainty lies in the randomness of the rates rather than in the Poisson type variation in the events themselves.

Logical Flaws in the High and Low Variants

Over the years it became customary to produce high and low variants, in addition to the most likely medium variant, to give the forecast users an indication of the plausible range of the future developments. Users have typically ignored the high and low variants. One reason has been the added complexity of having more than one number in a planning context. More fundamentally, an additional reason may have been that the high and low variants have not had a logically coherent interpretation. There are two reasons for this. First, suppose $[B_L, B_H]$ and $[D_L, D_H]$ are high–low intervals for births B and deaths D, respectively. In general, there is no guarantee that the two intervals cover an equal range, because no probability content for the intervals has traditionally been given. Any calculation based on intervals with incomparable ranges is difficult to interpret. Second, suppose that the intervals are given a probabilistic interpretation, so that the probability is, for example, 80% that each one of them contains the true value. This was first suggested by L. Törnqvist in 1949. Suppose there is no migration. Then the increase of the population is $I = B - D$. Unfortunately, one can show that the usual high–low interval $[B_L - D_H, B_H - D_L]$ for I has a higher probability than 80% to cover the increase. Only if the number of births and deaths have correlation -1 does the high–low interval have probability content 80%. But the assumption of perfect negative correlation is known empirically to be false.

In a traditional c-c forecast a very large number of vital rates are given high–low variants, and these are combined in complex ways to produce high–low intervals for population sizes at different ages. No uniform interpretation can be given to the latter intervals. For example, a United Nations forecast of the total world population published in 2010 gives a high–low interval of [7.9, 8.8] billions for the year 2030 and [8.1, 10.6]

for 2050. Since it is not known what probability contents these intervals are intended to have, it is not clear how they should be interpreted.

Expressing Uncertainty via Predictive Distributions

Modern probability theory provides a language that can be used to describe the uncertainty of the future vital rates and vital events in a consistent manner. This leads to a *predictive distribution* of the future population given what we have observed in the past.

The availability of fast computing allows the use of stochastic simulation to describe numerically the predictive distribution. In practice, this is done so that a set of age-specific vital rates is sampled from their respective predictive distributions. A c-c calculation is then made based on the sampled values to produce a possible *sample path* of the population in each age and sex group. This is repeated thousands of times and the results are stored. For any age–sex group, or for any larger population aggregate, one can represent the uncertainty of the forecast in terms of graphics (histograms, box plots, etc.), or in terms of statistical summaries (means, medians, standard deviations, etc.). Such techniques have been available for single region populations since the 1990s, and examples of their application for multiregional (or multistate) populations, household forecasts, and other functional forecasts have appeared in the 2000s.

The key element in such calculations is the formulation of the predictive distributions of the vital rates based on statistical analysis of the past data (Alho and Spencer, 2005). This can be based on formal time series methods of a frequentist or Bayesian type (Booth and Hyndman, 2008; Girosi and King, 2008), the analysis of the accuracy of the past forecasts (Keilman, 1990), and judgment (Lutz et al., 1998). Each method entails its own strengths and weaknesses.

Official stochastic population forecasts have been published in the Netherlands from 1999. The United Nations has produced probabilistic forecasts for all countries in the world since the 2010 World Population Prospects (Raftery et al., 2012).

Uses of Probabilistic Forecasts

Predictive distributions provide the forecast users with a richer view of the possible future developments than the traditional population forecasts. For users needing a point forecast only, one would typically offer the median of the predictive distribution. At the other end, a complete predictive distribution is available to a sophisticated user who may want to use it in macroeconomic calculations or *risk analyses*. Stochastic forecasts have been used in Europe and the United States in the analysis of the financial stability of pension funds and other social security systems. In practice, such applications require that suitable macroeconomic tools (e.g., generational accounting or computable overlapping generations models) are used in the context of a simulated predictive distribution of a population (Alho et al., 2008).

Abstract

Population geography grew as a subdiscipline of human geography to describe, analyze, and reflect upon the geographical organization of human populations. Contributing research on migration, population/environment/development links and transition theory, the growth of multidisciplinary approaches reflect broader interests in social difference, lifecourse, and population issues under a neoliberal and restructuring capitalist global system. Emerging discussions of transdisciplinarity may connect scholars inspired to research the interdependencies of societies' demographic, spatial, and political organization, and reinvigorate a heritage of service and interest in social justice.

Introduction

Many commentators regard population geography as the subdiscipline of human geography that describes, analyzes, and reflects upon the geographical organization of human populations (Trewartha, 1953; Clarke, 1965). Since Brunhes' preliminary discussion in 1910, the scholarship of population geography has varied along three axes: the degree to which studying the areal differentiation and geographic diversity of population could shed light on the unitary and holistic nature of place; the degree to which population was the apex of geography's concerns; the manner in which the field would coproduce knowledge with other academic specialisms (Bailey, 2005). In practice, it has been this last dimension that has stimulated the most debate. Hence, in reviewing the field's major contributions to social and behavioral knowledge, I emphasize how the field's traditional embrace of cross-disciplinary exchange between geography and demography has been supplemented by multi- and transdisciplinary approaches.

Spatial Demography

Clarke (1965: p. 2) argued that a clear disciplinary division of labor encouraged cross-disciplinary exchange: "[with its] emphasis particularly on space … population geography distinguishes itself from demography, which is the science of population viewed as a single topic." Thus oriented, spatial demography explored geographic variations in population, migration, population systems, and the role of modernization in population change.

Population Distribution

Geographic tools including visualization, areal classification, and spatial decomposition illuminate the diversity of population and the complexities of its uneven growth. Demography suggested that factors of fertility, mortality, and migration (from the balancing equation) and age–sex composition (from stable population theory) contributed to population diversity (Woods, 1982). Normative classifications used to further explore the components of diversity, including race, nationality, religion, education, occupation, family structure, urban–rural residence, development level, and customs (Trewartha, 1953: p. 88), gradually took center stage as objects of analysis (cross-reference to geography of youth, geography of race, children's geographies).

Visualizing population diversity continues to stimulate hypothesis testing. For example, neighborhood maps of the changing distribution of minority groups accompanied research on segregation and processes of population turnover. John Snow's map of cholera deaths surrounding water pumps in Victorian London's Soho district highlighted a cluster of cases and promoted further study on how one hand pump influenced the nature of disease transmission. As fresh public and commercial challenges arise, and as Censuses and surveys contribute new data, the production of such population maps proliferates. Recent applications draw attention to uneven life expectancies and the geographies of missing girl babies, female infanticide, aging, HIV-AIDS deaths and HIV-orphans, and childhood social exclusion. Geodemographic applications consider, for example, public and commercial facility location, emergency service management, and lifestyle marketing.

Demography and Economics of Human Migration

Among the three demographic components of change, migration receives the most attention in population geography. Migration flows are typically classified on the basis of motive (for example, voluntary vs forced, economic vs environmental), distance moved (for example, residential mobility vs international migration), and direction moved (for example, new vs repeat or circular). Statistical analyses use demographic rates (for example, migration rate) and spatially referenced indicators (for example, in- and out-migration, net migration, migration efficiency, and migraproduction rate, Clark, 1986).

Residential Mobility

Residential mobility is an influential component of local population growth and decline, with implications for service provision (for example, schools, clinics) and neighborhood change (for example, gentrification). The generally observed exponential distribution of the distance of such moves is cited as support for Ravenstein's observation that most moves are

close moves, and continues to stimulate social physics-inspired gravity modeling of migration flows. This stimulated the use of gravity models based on the social physics concept that interaction is a function of the size of places migrants move between and their relative proximity. Moreover, the commonly observed suburban-wards directionality to much (but not all) residential mobility was consistent with social ecological precepts used by Chicago-school sociologists. Less deterministic explanations emphasized the joint role of housing and family factors which, as Rossi and, later, Lee noted, unfolded in systematic ways through the life cycle. The role and price of information about opportunity and constraints emerged as a powerful locus of research, which accelerated the spatial application of microeconomic and push–pull frameworks. Cross-fertilized by Morrill's ideas about migration information fields and Wolpert's writing on place utility, Brown and Moore acknowledge the dynamic trade-offs that individuals make around such factors as accessibility to employment, housing, schools, and amenity. Such insights extended life cycle approaches by pointing to the strategies individuals used to manage risk and disappointment and learn-by-doing.

Regional Migration

Uneven and fluid patterns of regional growth, rural depopulation, urbanization, suburbanization, counterurbanization, nonmetropolitan growth, and the rise of ghost cities all have significant consequences for economic and political structures. In analyzing the distribution and dynamics of gross and net migration flows between regions, gravity models have been upscaled to consider regional structures (competing destinations), and nationally comparative work has pioneered the application of entropy theory to migration. Research has also developed accounting frameworks and multiregional models referencing cohort-based approaches themselves built on the concept of migration channels, which John Fraser Hart earlier used to explain patterns of African-American urbanization in the United States. The use of increasingly sophisticated estimates of disaggregated life tables, transition probabilities, and estimates of fertility and mortality for key subgroups provides critical information to local and regional governments on, for example, the impact of aging scenarios upon regional economies and housing demand.

Growing interest in different approaches to labor market policy stimulate research on the labor market behavior of particular groups of migrants, including unemployed and family migrants. Sjaastad's influential human capital account of migration proved flexible enough to explain why young people and some unemployed were more likely to migrate (longer time horizon over which to gain benefits), to inspire work on sex differences in returns to migration (Mincer's family migration framework hypothesized the wife's sacrifice), and to explain why many third world residents moved to areas of high unemployment (the Harris–Todaro model of rural to urban migration emphasized expected returns rather than actual wage differences).

International and Circular Migration

Long distance human migration is closely associated with differences in political cultures (for example, US, Canada, and Australia narrate themselves as 'classic' countries of immigration, and fiercely debate modes of migrant belonging including assimilation and multiculturalism) and development outcomes. The field's accounts of such migration are based on movements across officially recognized borders of nation-states, and have been organized into quite disparate camps. Refugees (more generally, forced migrants) were distinguished from economic migrants, who were themselves subdivided by level of skill (skilled and unskilled) and legal status (for example, guest workers, the so-called illegal/undocumented/irregular migrants). Explanations upscale accounts of, for example, skilled migrants being channeled between global cities, and refugees being propelled like billiard balls following the social physics logic of kinetic energy. International circulation assumes a commitment to return migration and is linked to the need for seasonal labor in livelihood systems that often predate colonially imposed borders. In these accounts, migrations are seen as outcomes of economic and political arrangements and as having limited impact upon these systems. Recent attention focuses on the expanding population of international student migration and international return migration, particularly among the second generation.

Population Systems

Widely applied in population geography, general systems theory calls attention to the interrelations of demographic flows and events within a given geographic area. Akinlawon Mabongunje explains why he felt a systems application to rural to urban migration in Nigeria could extend orthodox explanations: "one of the major attractions of this approach is that it enables a consideration of rural–urban migration as no longer a linear … cause-effect movement, but as a circular, interdependent, progressively complex, and self-modifying system" (1970: p. 16). His rural–urban migration system considered urban workers, urban consumers, communication systems, government development policy, agricultural practices, education policy, and social development. A similar approach has enabled research to analyze the links between internal (regional) migration and immigration, and how this affects the regional location and nature of new immigrant destinations, the changing nature of segregation, and the direction of causality between migration and labor market change. A cross-national inventory of local and regional accounts of new immigration communities has arisen, alongside more system-oriented analyses of the changing role of regions, gateways, and spatial structure in a national economy.

Systems approaches also stimulate research on links between population and environment. At a national and regional scale, this includes the neo-Malthusian 'Limits to Growth' model, and the 'IPAT' framework, which models impact as a function of population, affluence, and technology in a region. At a regional and local scale, John Hunter's field-based analysis of the Nangodi region of Ghana revealed that, between 1948 and 1960, population declined by 15%, despite the availability of medicines and falls in mortality. The immediate cause was sex selective outmigration to southern cities, triggered by overpopulation. This arose as river blindness spread into Nangodi and reduced the cultivable land area, putting intense pressure on the regional livelihood system

(reviewed in Bailey, 2005: p. 100). This approach resonates more generally with Ackerman's notion of resource regions, and emphasizes how regional systems contain interdependencies between population, resources, and technology that can be offset through the movement of demographic (migration) and nondemographic (trade) factors of production.

Modernization and Population Transitions

Population geography adds a spatial dimension to accounts of how modernization leads to systematic population transitions. The classic demographic transition model describes a hypothetical sequence of changes in a country's population from a high fertility–high mortality–low growth rate regime to a low fertility–low mortality–low growth rate stage. In postulating two intermediate phases, where mortality falls more quickly than fertility, and overall growth increases, studies have focused on the diffusion of modern sanitation and antibiotics, and processes of secularization (for example, the adoption of a norm of a smaller family in urban society). By regionalizing areas (countries) with similar mortality and fertility dynamics, scholars establish expected speeds of transition and draw attention to deviations from such norms. For example, noting transition disparities in societies with below replacement fertility, rapid immigration, demographic aging, where fertility has declined with no increase in economic development, and where mortality has increased to levels seen a 100 years ago, research now attends to the mediating role of population composition, including family structure, ethnicity, and age profile. Discussions of the so-called second demographic transition are located within a broader agenda considering demographic convergence. Critics point to the value-laden assumption that Western concepts of secularization and ideal family size apply universally, without reference to local culture.

Modernization affects uneven spatial patterns of mortality and morbidity through developments in nutrition, manufactured products, medical advances, public health provisions, and patterns of disease distribution. Research considering the case of HIV-AIDS has greatly complicated the glib assertion that the diffusion of medical technology plays the driving role in the epidemiological transition. As he vividly illustrates for Haiti, Paul Farmer (1999) argues diffusion is a spatial process that is socially mediated: "AIDS in Haiti is all about proximity not distance. AIDS in Haiti is a tale of ties to the United States…about steep grades of inequality, both local and transnational. AIDS in Haiti has … to do with the pursuit of trade and tourism in a dirt-poor country" (p. 126).

Zelinsky's mobility transition similarly investigates the systematic rhythms of migration that accompany the onset of modernization. He tracks shifts from a localized population with little internal movement, through a phase of falling mortality and rising growth rate, to a more urban system with much rural to urban migration (and frontier migration in developing economies, Bailey, 2005: pp. 92–94). As one idea of modernization diffuses – the idea that spatial and social mobility can be substituted – he argues urban to urban migration also diminishes, to be replaced by circulation. His framework stimulates research on, for example, how and when rural fertility regimes change in response to outmigration, and how communication technology absorbs geographic mobility.

Population Studies

The rise of multidisciplinary accounts has accompanied the wider use of the term population studies by many practitioners, and a set of critiques about the empiricist and positivist bases of spatial demography (White and Jackson, 1995). One concern is the paradox that, despite being about population, people (their agency, their suffering, etc.) are often absent from many accounts. Moreover, the use of normative classifications and a focus on events may obscure the complexity of social processes, and lead to unhelpful essentialization of population groups. Similarly, the field's treatments of space can be superficial and uninspired. Taken together, and particularly influenced by feminism and neo-Marxism, an emerging multidisciplinarity in population geography shared at least three features: a desire to give greater attention to debates within human geography, particularly about the role of space and place in social life; an appetite for pluralism and the use of concepts, theories, and methods from areas such as sociology, anthropology, political science, gender studies, postcolonial studies, critical race theory, and development studies; a tolerance of thematic specialization. While by no means exhaustive, four areas where such multidisciplinarity grew include population geographies of the lifecourse, environment and development, difference, and sociospatial relations.

Lifecourse

Partly inspired by behavioral and feminist critiques of the deterministic role of age in life cycle models, population geographies of the lifecourse emphasize the patterns of order and order of patterns in the practices of everyday life. Like Hagerstrandian and time geographic approaches more widely, the lifecourse provides a framework for understanding interdependencies between: population events (including the act of moving, partnering, becoming unemployed, graduating); careers (including residential locations, migration decisions, employment, family life); linkages between lives and between institutions; the learned and social nature of time. The fecundity of such a lens is suggested by, for example, growing interest in the process of studentification as lifecourse planning. This debate straddles the intersection of formerly separate categories of analysis (life cycle nest-leaving, rental housing choices, international migration), while powerfully shaping the way housing markets function, the acquisition of cultural capital by transnational families, changing subject positions within extended households, immigration policy, and community relations. Another emerging debate on time squeeze references diverse factors like the rise of dual career couples, traffic congestion, the sandwich generation, and social media and studies how the changing expectations of, and realities of coordination and synchronization reproduce gender relations, age relations, and familialism.

A connected thread of lifecourse research explores the structural nature of population inequalities by examining how events and experiences at one time impact subsequent outcomes. Comparisons between population groups (cohort-based by socialization, race and ethnicity-based, class-based etc.) show how context affects the ways in which early life medical conditions, education investments, and migration

behaviors affect later life opportunity and outcomes. The approach draws attention to how healthy places reduce morbidity, defamilialization and how population experiences vary across welfare regimes, how visa regulations affects family reunification and ongoing subject positions within families, and how population events become embedded and transmitted as cultural survival strategies in ecologically dynamic regions such as the Sahel.

Environment and Development

Multidisciplinary analyses have extended traditional notions that population events are crisis responses to environmental changes and that population phenomenon can independently trigger ecological transformation. Whether narrated as a population–environment–development nexus, a population–environment nexus, a population–development nexus, or a migration–development nexus, the field uses ideas from political ecology about the dialectics of nature society relations, resilience and adaptability, and the nature of ecological regulation by the state and other bodies (Findlay, 2005). Research analyzes the vulnerabilities that populations experience in and through their ecological settings and practices, and the structures of adaptability and resiliency that emerge.

Explorations of the cultural and interdependent nature of the population geographies of environment and development also accompany the rise of a more progressive cultural ecology in the field. This studies how ecological change can influence gender, class, and ethnic/racialized positions, with implications for population structures. For example, Gray and Mueller (2012) use rural-household survey data to show how place-based gender norms mediate the migration response to drought in Ethiopia. They report that male outmigration increases for livelihood reasons but the same local shortages of capital restrict the potential for dowry payments and limit female marriage migration. Indeed, as situations of ecological collapse may require young males to outmigrate (and remit) or be deployed to more risky means of livelihood, either response changes their gendered position of influence, such that ecological, class, and gender systems are recalibrated. Careful ethnographic and empirical analysis reveals similar cultural transformations in the context of forced displacement from dam and infrastructural projects.

In exploring the cross-cultural ways in which adaptability and resilience is understood and transmitted through norms and practices, population geography draws attention to how local discourses may counter hegemonic, often neoliberal understandings of how certain population groups may need 'protection' from hostile environments and, more controversially, from their own 'local' practices. The field similarly contributes a more spatial and politically aware discussion of population as 'the elephant in the climate change room.' Research attends to how spatial context affects the interdependencies between climate change inputs, including droughts, floods, extreme events, shifts in the ecumene, and population, migration and, in turn, geopolitical consequences (for example, famine-induced conflict). More broadly, the need to carefully model complex relations between environmental, economic, and social systems has stimulated the development of Geographical Information Science and spatially disaggregated, longitudinal, and historical climate models. Through offering sophisticated analyses of ecological, population, and cultural interdependence, the field can counter overly economic and neo-Malthusian accounts of climate change and may provide ammunition for those who wish to diffuse hysterical media hype around, for example, floods of environmental refugees and climate-induced wars.

Difference

Inspired by feminist and critical interpretive approaches, the field contributes to understandings of how population categories, including events, groupings, and distributions, are social constructions rather than normative structures. This project is intimately tied to humanities research on the nature of social difference, including gender, race, ethnicity, age, sexuality, and disability. One thread looks at how families, states, and other social institutions originate and mediate discursive productions, which affect identity, with research-exploring gendered migration (Silvey, 2004) and the place-based othering of queer communities, asylum seekers, and Romani travelers (Tyner, 2009). For example, Anderson (1987) shows how an idea of Chinatown emerges as a state constructed population category, which circulates further, explicitly racialized discourses.

Ongoing research on the ascribed identities of diasporans accents their subject positions as cosmopolitan elites and patriotic remitters, and probes the racialized manipulation of discourses of belonging and home that states regard as influential in exploiting their economic contributions. The intensification of transnational, cross-border activity has significant consequences for gender, ethnic, racialized, faith-based, family-based, and political identities, which in turn transform social structures (including split families, astronaut families), cultural structures (including ethnoscapes, faith-based community networks), economic structures (notably the impact of remittances upon livelihoods, communities, and the growth of the migration–development nexus), and political structures (including institutions of governance, multiculturalism, citizenship, and the trajectory of the European suprastate). Regarding citizenship, the intersection of gender, ethnicity, and class (employment type) brings systematic disadvantage for women migrants in accessing family reunification provisions. Indeed, such research on intersectionality has stimulated further interest in *how* identities come together in particular spaces and places at particular times (Silvey, 2004).

Most widely, population geographies of difference accent the role of space in negotiating identity, intersectionality, and for promoting identity politics. For example, discussions of segregation and NIMBYism have laid bare the social norms held by the public and state concerning how certain population groups should organize themselves spatially and temporally. In the UK, the multidisciplinary debate about the extent to which minority groups and natives lived 'parallel lives' and society was 'sleepwalking into segregation' turns on spatial expectations about the speed of assimilation and the persistence of the so-called ethnic ghettoes (cf underclass debate in the United States). The relevance of context is also shown by work on the uneven embodiment of transmigrant life, and how transnational networks are not blank deterritorialized canvasses, but

actively reterritorializing networks of networks (Dunn, 2010). Such emplaced performances have been studied through accounts of visual and material cultures in the home, and comparative analyses of language use in home and classroom settings.

Sociospatial Relations

Research on the sociospatial relations of population geographies locates the recursive connections between identity/belonging and space/place/network within broader concepts of capitalist restructuring. Population organization and strategy has been tied to capitalist rescaling in work on everyday transnationalism. Examining Chinese globalization Pieke et al. (2004: p. 162) show how Fujianese migrants create a transnational social space from below that is rooted to both China and Europe: "through practice and discourse [migrants] are tied to a transnational social space that spans the globe…[and] configures the perspective through which migrants look at the geographic locations that migration brings them to." By changing geographic perspectives migrants rescale the networks connecting China and Europe, and have the potential to shift neoliberal political structures (cf the more deterministic treatment of flexible citizenship in other accounts of Asian mobilities under exceptional neoliberalism, Bailey, 2005). The broader point, expressed cogently by Ley in his analysis of the performed sociospatial relations of trans-Pacific migrants (2010), is that migrant rescaling goes beyond the crude binary categorization of globalization, and free mobility versus localism and constraint. Such transnationalism is not just 'from below' or 'from above' but always situated, placed, and transformative.

Similar themes run through research on the population geographies of vulnerability. Populations exposed to structural risk, be it economic (contemporary global recession), cultural (hate crimes and xenophobia), or environmental (for example, the Indian Ocean tsunami) reproduce sociospatial relations, which transform political, social, and religious institutions; the nature of borders and bordering processes; and shape capitalist restructuring (Findlay, 2005). Another debate examines if and how migration and state constructions of overseas workers respond to, or drive the structure of labor markets and systems of global cities (Tyner, 2009). In contrast to orthodox research that argued skilled migrants moved according to human capital and contractual dictates, and in the direction of global capital, analyses of the sociospatial relations of contemporary international mobility shows distinctive links between skilled and unskilled migration flows, the rise of global care chains, the appearance of a migrant division of labor, distinctive second generation return mobility, and transformations in the nature of work that undermine the long-held distinction between temporary/informal and permanent/formal labor.

Transdisciplinary Population Geographies

Transdisciplinarity aspires to transformational conceptual engagement between and across disciplines and knowledge partners, and often uses case-driven methods to reorient the politics and ethics of knowledge. While method was ontologically unproblematic for spatial demography, pluralism and specialization associated with multidisciplinarity made it harder for practitioners to articulate a cohesive position on population matters. With the cultural turn in human geography igniting a debate about relevancy, signal events like 9/11 derailed an abstract and dry globalism that proclaimed the local and global interdependence of lives and rerouted it as a globalism bristling with menacing and threatening population issues, including disaffected immigrant youth, ecological refugees, global pandemics, NEETs, and a pensions crisis. Within the field, Philo (2005) urges scholars to not just pay lip service to ideas such as vulnerability, but to inspect what lies beyond the label, i.e., chains of influence and power. Tyner (2009) imagines new solidarity networks around topics, themes, forms of measurement, across disciplines, and between universities and their local communities. In practice, and using preliminary examples concerning violence, and bodies, transdisciplinary population geographies have acknowledged the global, cross-cultural production of knowledge, the possibility of an emerging global consciousness, and the need for an ethical intervention – a view from somewhere.

Violence

Drawing on different elements of the diverse corpa of Michel Foucault and, to a lesser extent Henri Lefebvre, a number of population geographers have studied the systematic, historicized, and placed relationships between population, inequality, and power. A growing number of studies examine how members of population groups, including migrants, experience vulnerability arising from security concerns. Post-9/11, post-transnational fluidity, and under global recession, such others are not just different, but threatening. Mountz (2010) explores why one group of migrants – those smuggled – come to be seen as 'exceptional,' and what this means for their lives. She uses a bespoke institutional ethnography to 'study up' how the daily actions and narratives and silences of individuals associated with state regulation of immigration and asylum in Canada have shifted the population geographies of protection for smuggled asylum seekers. Her framework draws widely on literature in geography, anthropology, sociology, and political science to interrogate 'the long tunnel thesis' whereby 'arriving migrants' (i.e., those interdicted in Canadian waters) would be treated as if they were walking through the long underground corridors of an airport, always approaching but never quite landing (Mountz, 2010: p. xiv). Tyner's treatment of violence seeks to: "emphasise the production of knowledge claims that legitimize and justify the perpetuation of violence through the marginalisation of bodies and populations" (Tyner, 2009: p. 45). Tracing the manifestation of violence through war, he considers the cases of rape of Tutsi women, the killing fields of Cambodia, and the body count in Viet Nam. He extends the Foucauldian concept of biopower by combining anatomopolitics (separation and discipline through classification) and biopolitics (including the exercise of state power through manipulations of what counts as a population and what counts as a population event, including death).

Bodies Making Population

By holding that emplaced and practiced performances rework social and cultural norms and relations between constituting institutions researchers reposition populations and their acts (things like childbirth, moving, staying put, dating, being represented) as questions of bodies in/through space. A focus on embodiment points out that bodies do not just appear/happen, but come with messy materialities, such that space and place is a lived and vital part of any population (act/being). In the recent Body/State, Cameron et al. (2013: p. 2) further interrogate the roles of states, noting: "this book has come into being because … there has been a proliferation of ideas, insights and knowledge surrounding the biopolitics of bodies across an ever-widening range of social, political, and academic concerns." Their empirical matter discusses female circumcision, hunger strikes, organ transplants, body monetization, male sex work, the disabled body, picketing and unruliness, home-schooling, the biopolitical regulation of liminal transsexual bodies, pitied bodies, unmapped bodies, and virtual bodies. For Longhurst et al. (2009), participating with migrants in New Zealand in cooking a symbolic dish illuminated daily experience as a set of embodied and scaled relations of body–mind, biology–social, edible–nonedible, here–there, and human–nonhuman. Such research has the potential to expand the dimensions on which difference – but also connection – is understood, with Rosi Braidotti offering a tantalizing glimpse of how embodied and emplaced subjects are critical to counter contemporary, false proclamations of social progress. Noting that "advanced capitalism has consumed and subsumed the old gender system," and drawing on Deleuze's concept of empirical transcendental, her nomadic theory calls for research on: "power relations that construct technologies as liberating while using them for the most confining, profit-making, war-seeking, and sexually-conservative ends" and focuses on bodies as nomadic subjects that reject liberal individualisation and connect with respect for complexity and interconnection – "a collectively-oriented, externally-bound, multiple subject" (2011: p. 79).

Conclusion

Ebbs and flows in the popularity of the term 'population geography' mask a persisting commitment to, and ever wider production of spatial demographic knowledge about populations in their spatial settings. Yet, as academic divisions of labor evolve, and public and political consciousness about population softens and hardens, multidisciplinary and transdisciplinary scholarship further expands the approaches, topics, and ethics of the field. It perhaps seems fair to suggest that population geography is becoming a community of practice that can connect scholars inspired to research the interdependencies of societies' demographic, spatial, and political organization, significantly drawing on a heritage of service and interest in social justice. Drawing together diverse knowledge from diverse places, all the time making a difference, may require new approaches to activities many may consider beyond the scope of a subdiscipline, including having impact in a neoliberal landscape, and inspiring students with discussions of peace and activism.

Abstract

The question 'How many?' arises in many scientific areas. To address this question, Capture–recapture studies are often used to partially observe the population of interest. In these studies, several sources are used to observe individuals in the population, which are subsequently collated together and the data summarized by the number of individuals observed by each distinct combination of sources. Statistical models are fitted to the observed data, permitting the estimation of the number of individuals not observed by any of the sources, and hence (when combined with the number of observed individuals) the total population size.

Introduction

The question 'How many?' arises in many different scientific areas. For example, "How many leopards are there in a given jungle/area?," "How many injecting/problem drug users are there in Glasgow and/or Scotland?," or even "How many typographical errors are there in a given text?." Unfortunately, identifying and enumerating all the given members of the population of interest is typically infeasible or often simply impossible for numerous reasons.

An early attempt to address this question of 'How many?' was made by Laplace in 1786 who wished to estimate the population of France. The underlying idea that was used is as follows. Consider a subgroup of the population of interest, where the size of this subgroup is known to be n_1. Randomly sample n_2 individuals from the whole population of interest and record the number of individuals that are also in the subgroup, denoted m_2. (Laplace used the register of births in France for the subgroup of known size, and parish registers for the subsequent random sample of the whole population.) Under some assumptions (see below), the proportion of individuals from the sampled population that are in the known subgroup should be equivalent to the proportion of individuals from the whole population that are in the given subgroup, so that

$$\frac{n_1}{N} = \frac{m_2}{n_2}$$

Rearranging the equation gives an estimate of the total population size of $\widehat{N} = n_1 n_2 / m_2$. For many applications, the subgroup itself is obtained by taking a random sample of individuals from the total population at a given capture event/occasion, which are subsequently marked to make them identifiable. This corresponds to an initial capture event, the subsequent resampling of the population corresponds to the recapture event. This description leads to the commonly used name capture–recapture (or mark–recapture).

The above estimate of the total population size is typically referred to as the Lincoln–Peterson estimate. A number of assumptions are made, including (1) the population is closed between capture occasions (i.e., there are no births/deaths/migration within this period); (2) all individuals in the population have the same capture probability at each capture event; (3) at the recapture occasion all previously observed individuals can be identified (i.e., there is no mark loss). The Lincoln–Peterson estimator is a consistent estimator of the total population size, however, it is biased for finite sample sizes. This has led to the Chapman estimator (Chapman, 1951):

$$N = \frac{(n_1 + 1)(n_2 + 1)}{(m_2 + 1)} - 1$$

which has smaller bias. See, for example, McCrea and Morgan (2014; Chapter 3 and references therein) for further discussion of the Lincoln–Peterson estimator and underlying assumptions. Note that this two sample capture method is also referred to as the dual system estimation problem.

Multiple Recaptures

The previous two sample capture–recapture experiment can be extended by taking multiple recapture events. The study design is as follows. At the initial capture occasion all observed individuals are uniquely marked and released back into the population. At each subsequent capture occasion all observed individuals are recorded, previously unmarked individuals are uniquely marked, and all individuals released back into the population. The data obtained correspond to the set of capture histories for each individual observed within the population, detailing at which capture occasions each of the individuals are observed. For example, suppose that there are 10 capture occasions and a given individual is initially observed at time 2 and subsequently observed at capture occasions 3, 4, and 9. Their corresponding capture history would be represented as:

0 1 1 1 0 0 0 0 1 0

The 0/1 indicates that the individual is unobserved/observed at the given capture occasion. This experimental design is typically undertaken with ecological studies, where the capture occasions correspond to capture events, where observers go into the field and record all individuals seen within a given period of time. However, for other populations of interest, notably within epidemiological applications, including human populations, the capture occasions typically

refer to different 'sources' or 'lists' that can observe individuals. The corresponding capture history details the set of sources that have observed each individual in the study period. Thus for such studies, the capture histories do not provide any temporal information. For example, for the given capture history above, this would correspond to an individual being observed by sources 2, 3, 4, and 9, but does not indicate the order in which they were observed by the different sources. This naturally leads to different forms of models for ecological and epidemiological studies (see below). For simplicity we will generally use the term 'source' to refer to all of the different forms of capture occasions, however, we do revert back to the use of capture occasions/events in the context of ecological studies.

Capture–recapture data are often summarized (particularly when the number of sources is small) via the form of an incomplete 2^k contingency table, where k denotes the number of sources. The factors of the contingency table correspond to the sources, each of two levels corresponding to being observed or not observed. The cell entries correspond to the number of individuals observed by a given combination of sources. The contingency table is incomplete as the number of individuals in the population not observed by any source is unknown. **Table 1** provides an example of an incomplete contingency table using three different sources (Hook et al., 1980).

Statistical models can be fitted to the observed data of the incomplete contingency table, which then permit estimation (or prediction) of the unobserved cell entry. This estimate of the unobserved cell is combined with the total observed number of individuals in order to obtain an estimate of the total population size. These statistical models are dependent on the form of the sources used (i.e., epidemiological capture sources or ecological temporal capture occasions) and the underlying modeling assumptions. The models are fitted to the data, and inference obtained, either via the calculation of maximum likelihood estimates (MLEs) or via the Bayesian posterior distribution of the model parameters with associated posterior point estimates presented, such as the posterior mean or median (see below for further discussion of the Bayesian approach). The estimate of the total population size is usually presented with an associated uncertainty interval, namely, a confidence interval for the classical approach or a credible interval for the Bayesian approach. We discuss the associated models in more detail next.

Table 1 An example of a 2^3 contingency table for babies born with spina bifida in New York State between 1969 and 1974 presented by Hook et al. (1980). Source 1 corresponds to birth certificates, source 2 to death certificates, and source 3 to medical records. For example, 12 individuals are observed by all three sources and 142 individuals are observed by sources 1 and 2 but not source 3

		Source 3	
Source 1	*Source 2*	*1*	*0*
1	1	12	142
1	0	112	247
0	1	4	49
0	0	60	?

Models

A range of models have been proposed to fit to capture–recapture data to incorporate different underlying assumptions, and in particular different forms of heterogeneity. We present these separately for ecological (temporal) capture–recapture studies and social/epidemiological (nontemporal) capture–recapture studies. Chao et al. (2001) provide a summary and comparison of many of these models.

Social/Epidemiological Capture–Recapture Studies

For social (or epidemiological) capture–recapture studies the capture sources often relate to different 'registers' or 'lists' that each attempt to enumerate the number of individuals in the population of interest. These often relate to hidden (or difficult to observe) populations of societal interest, such as problematic drug users, individuals with a given disease, the number of homeless individuals in an area, etc. Registers of such individuals are often compiled by a number of different agencies that can be cross-classified to form the incomplete contingency table using identifiers such as initials, date of birth, postcode, etc. to uniquely identify each observed individual. For such data the sources (or registers) are in general not independent of each other. For example, if an individual is observed by one register then they may be more or less likely to be observed by another register, leading to the idea of a two-way interaction. For any two given registers, there is said to be a positive (or negative) dependence if an individual is more (or less) likely to be observed by one register if they are observed by the other register (and vice versa). Assuming that the registers are independent will lead to an overestimation in the total population size if two sources are negatively dependent and an underestimation if two sources are positively dependent. Higher-order interactions (i.e., three-way, four-way, etc.) are also possible, that are able to represent more complex relationships between the registers. Such interactions are able to represent relationships corresponding to the propensity of being observed by one register being dependent on the combination of other registers that an individual is observed by.

Log-linear models specify the contingency table cell entries to be independent observations from Poisson distributions, where the corresponding log of the expectations are a linear function of main effect terms, corresponding to the capture propensity of each source, and interaction terms (Fienberg, 1972). In general, for such incomplete contingency tables, when there are k sources, interactions up to order $(k-1)$ may be estimated (when there are only two sources, so that $k=2$, it is not possible to consider an interaction between the sources, and they are assumed to be independent). For example, when there are three sources, denoted A, B, and C, there are three possible two-way interactions that can be estimated, corresponding to each pairwise interaction between the three sources, AB, AC, and BC. In addition, there are eight possible log-linear models, corresponding to the inclusion/exclusion of each of these interactions (see below with regard to model selection). Note that, typically, only hierarchical log-linear models are considered – these are defined such that if a given interaction is present in the model, all of the corresponding associated lower-order interactions (and main effect

terms) are also present. Graphical models and decomposable graphical models are often also considered due to their associated properties, and are special cases of hierarchical log-linear models. For a given log-linear model, the associated likelihood function can be constructed and an estimate of the total population size obtained (either using maximum likelihood or a Bayesian approach). Bishop et al. (1975) provide detailed descriptions of log-linear models for capture–recapture data.

Categorical covariate information is often collected on the observed individuals within the study. For example, gender, geographical region, and/or age-group (as noted above these are often used to uniquely identify individuals permitting cross-classification across different registers). In the presence of such covariate data, when it is believed that the different subclasses may represent different capture propensities for (and/or interactions between) the different registers, it is commonplace to stratify the data, corresponding to the set of categorical covariates. This leads to multiple incomplete contingency tables, corresponding to each combination of categorical covariates. Traditionally, each individual's incomplete contingency table is analyzed independently of each other, providing an estimate of the total population size for each combination of categorical covariates. However, stratifying in this manner can lead to 'small' contingency tables (in terms of the cell entries, including zero cell entries) and unstable estimates of population size. An alternative approach is to construct a single incomplete contingency table, where each covariate is regarded as a factor (note that the resulting contingency table has multiple unobserved cells). Log-linear models are defined in the standard way with additional main effect terms for the new categorical covariates and associated interactions (of only covariates, or covariates and registers). For example, see King et al. (2014) for such data relating to injecting drug users in England, where additional two-level covariates of gender and age-group are considered.

Ecological Capture–Recapture Studies

For ecological capture–recapture studies, there is a temporal component to the survey design, with captures of individuals associated with a given (ordered) set of capture events/occasions. Otis et al. (1978) described three possible forms of heterogeneity that may affect the associated capture probabilities: temporal (t), behavioral (b), and individual (h) heterogeneity. Temporal effects relate to variability in capture probabilities across occasions (for example, due to environmental conditions, changing survey effort, etc.); behavioral effects corresponding to a change in an individual's capture probability following their initial capture (an increase in capture probability is referred to as a 'trap happy' response; a decrease as 'trap shy'); and individual heterogeneity corresponding to variability in capture probabilities across individuals.

A common modeling approach is to specify the capture probabilities to be of logistic linear form. For example, let p_{it} denote the initial capture probability for individual i at time t; and c_{it} the recapture probability (i.e., their capture probability following their initial capture). The logistic linear model allowing for temporal, behavioral, and individual heterogeneity specifies the initial capture probabilities to be of the form

$$\log\left(\frac{p_{it}}{1-p_{it}}\right) = \alpha_t + \gamma_i$$

with associated recapture probabilities, $\log\left(\frac{c_{it}}{1-c_{it}}\right) = \log\left(\frac{p_{it}}{1-p_{it}}\right) + \beta$. The term α_t denotes the temporal effects; β the behavioral response ($\beta > 0$ corresponds to trap happy; $\beta < 0$ to trap shy); and γ_i the individual effects. Submodels, excluding a given heterogeneity is obtained by setting constraints on the parameters and/or terms equal to zero. For example, if there is no temporal heterogeneity, $\alpha_t = \alpha$ for all capture times t; if there are no behavioral effects, $\beta = 0$; in the absence of individual heterogeneity, $\gamma_i = 0$ for all individuals i. The temporal effects are essentially equivalent to the main effect terms for log-linear capture–recapture models; and the behavioral effects can be viewed as a constrained set of log-linear interaction terms. The Rasch model is a special case when there are only temporal and individual heterogeneity effects present (i.e., $\beta = 0$), which can also be viewed as a log-linear quasi-symmetry model (Fienberg et al., 1999).

For models with only temporal and/or behavioral heterogeneity, there is an explicit likelihood function. In the presence of the individual heterogeneity component, additional complexities arise. Specifying distinct (arbitrary) individual parameters (i.e., γ_i values) does not permit the total population size to be estimated (how do we know what the individual parameter values are for the unobserved individuals?). To incorporate individual heterogeneity, finite or infinite mixture models are typically assumed for the individual component terms. Finite mixture models specify the population to be composed of a set of homogeneous subpopulations, such that within each subpopulation individuals have common capture probabilities (see for example, Pledger and Philpot, 2008). For infinite mixture models (also called random effects models), the individual capture probability component is assumed to be a random sample from some distribution. The individual effect terms (i.e., the γ's in the above) are integrated out numerically or analytically, dependent on the model specification, within the corresponding likelihood expression (see, for example, Coull and Agresti, 1999; Dorazio and Royle, 2003). Additional individual-level covariate information can be incorporated within the logistic regression, permitting the capture probabilities to be dependent on additional factors (Huggins, 1989; Alho, 1990).

Bayesian Paradigm

The above statistical models can be fitted to observed data and the MLEs of the model parameters calculated, providing an estimate of the total population size. However, recently, there has been increasing interest in the development of Bayesian model-fitting approaches. The underlying philosophy of the Bayesian approach is that parameters are random variables (as opposed to fixed but unknown quantities in the classical framework). The mechanics of Bayesian inference are as follows. We begin with a prior distribution: this represents our beliefs and uncertainty about the model parameters prior to

collecting the data. Once we have collected the data, we evaluate the posterior distribution by combining the information from the data (via the likelihood function) with the prior distribution using Bayes theorem:

$$\text{posterior} \propto \text{likelihood} \times \text{prior}$$

The posterior distribution represents our updated beliefs and uncertainty about the model parameters, in light of the observed data. Bayesian approaches have been developed for both social/epidemiological and ecological capture–recapture studies (see, for example, Madigan and York, 1997; King and Brooks, 2001, 2008).

The philosophy of the Bayesian approach means that probability statements can be used to quantify uncertainty in the model parameters. For example, a 95% credible interval for the total population size will contain the total population size with probability 0.95. These types of statements are typically easier for scientists and epidemiologists to interpret than the corresponding statements under the classical approach where model parameters are fixed but unknown (i.e., relating to confidence intervals). In addition to the interpretability, a further advantage of the Bayesian approach is its ability to incorporate (independent) external information through the prior distribution, fully incorporating all available information within a formal framework. For example, King et al. (2014) are interested in the number of injecting drug users in England. They use independent data corresponding to the number of drug-related deaths attributed to injecting drug users and associated prior expert beliefs on the injecting drug-related death rate to form a prior distribution on the total population size of injecting drug users. In the absence of any prior information on the model parameters, uninformative (or vague) priors are specified on the model parameters.

Model Selection

The estimation of the total population size is generally highly dependent on the model fitted to the data. For example, for log-linear models, this corresponds to the set of interactions that are present in the model; for logistic regression models, the heterogeneities that are assumed to be present in the capture probabilities. Thus, within an analysis of the capture–recapture data, the first step is usually to determine, or select, the model. One possible approach is to fit the saturated (most complex) model to the data. However, this often leads to low precision and unstable estimates of the total population size. Thus, in general, the idea of parsimony is advocated. This approach essentially involves finding the 'simplest' model that is deemed to adequately fit the observed data. A range of parsimonious model selection criteria exist. Within classical statistics, likelihood ratio tests can be used to compare nested models (i.e., where one model is a special case of the other model). More generally (including for non-nested models), information criteria can be used. Information criteria are defined such that there is a trade-off between the fit of the model to the observed data (usually defined via the deviance) and the corresponding complexity of the model. The most commonly applied information criterion for capture–recapture data is Akaike's information criterion (AIC), and associated variants, including corrected AIC (AICc) and quasi AIC (QAIC) for small sample sizes and overdispersed data, respectively (Burnham and Anderson, 2002). Within a Bayesian framework, models may be quantitatively compared via posterior model probabilities or Bayes factors.

Ideally, for a given model selection criterion, such as the AIC statistic, each possible model should be fitted to the data in turn. The (final) model chosen is the model that is deemed optimal for the given model selection criterion, and the corresponding estimate(s) for the model reported. However, fitting all possible models to the data is often infeasible, due to the total number of models. In these circumstances, a model search algorithm is often implemented using a 'bottom–up' approach (starting in the smallest model and proposing to add terms one at a time) or a 'top–down' approach (starting in the saturated model and proposing to remove terms one at a time), or some combination of these approaches. However, this does not guarantee that the optimal model will be chosen. Automated (and stochastic) computational algorithms have also been developed to search over the set of possible models in order to identify the optimal model.

Providing an estimate of the total population size conditional on only a single model, deemed optimal via some model selection criteria, assumes that the model identified is correct. This, in turn, may lead to an undesirable overconfidence in the estimate obtained of the total population size. An alternative approach is to provide a model-averaged estimate for the population size. Such estimates involve using a weighted average of the estimated total population size for each possible model, thus accounting for model uncertainty in the estimation of the total population size. For example, within classical analyses, AIC weights are often advocated; within Bayesian analyses the weights correspond to the posterior probability of each model. Model-averaging approaches have been applied to both social and ecological capture–recapture studies (see, for example, Madigan and York, 1997; King and Brooks, 2001, 2008).

Statistical Software

In order to implement the statistical techniques and models to analyze data, a range of (more-or-less) user-friendly computer packages have been developed (Bunge, 2013). These may be in the form of stand-alone packages, or packages developed for standard software, such as the freely available statistical software R. In particular, these include the R package conting (Overstall and King, 2014) for Bayesian log-linear analyses and the stand-alone package MARK (White and Burnham, 1999) for ecological capture–recapture models. Such packages permit the fitting of many of the standard models presented above for capture–recapture data.

Relaxing the Assumptions

Any statistical model that is fitted to data makes certain underlying assumptions. These assumptions may or may not be able to be assessed as to their validity (for example, the validity of the extrapolation to unobserved individuals, given the observed individuals is untestable). In order to assess, or remove, a given assumption, additional statistical models have been developed, extending the traditional capture–recapture models.

For capture–recapture data, the construction of the capture histories of the observed individuals, and hence incomplete contingency table data itself assumes that all individuals are correctly matched across different sources. However, what is the confidence attributed to the matching of individuals across the different sources: are any mismatches likely to occur? If so, are these more/less likely to be for given sources, or are they simply random occurrences across each source? Mismatches can lead to false positives (two distinct individuals identified as the same individual by two different sources) and false negatives (the same individual identified as two different individuals by two different sources). For social applications, an individual may have his/her name spelt differently by two different registers, leading to them failing to be matched as the same individual when the sources are collated (a false negative) or two distinct individuals with similar names being incorrectly identified as the same individual (a false positive). See Fienberg and Manrique-Vallier (2009) for a discussion of these issues. Within ecological capture–recapture data studies, traditionally physical marks have been applied to individuals so that they are uniquely identifiable. However, photo identification and DNA profiling are becoming increasingly popular due to their noninvasive nature but may lead to false positives/negatives (see, for example, Wright et al., 2009 with regard to DNA genotype matching).

The sources used to obtain the capture histories may also raise issues. For example, individuals observed by the given registers are assumed to be identifiable as to their membership of the given population of interest. However, this may not always be the case. For example, Overstall et al. (2014) use a hepatitis C virus database as a capture–recapture source for identifying injecting drug users. This database identifies injecting drug users as those individuals who specify the potential source of contracting hepatitis C as injecting drugs. However, the population of interest is that of current injectors only, so that this database also records past injectors who are no longer injecting, and hence not in the population of interest. Standard capture–recapture models can be extended to directly model such additional data complexities (Overstall et al., 2014).

Many other issues may arise with regard to the associated modeling assumptions, and should be assessed for their validity for any given problem. For example, in the estimation of total population size, the above models all assume that the population is closed (i.e., there are no births/deaths/migrations). For studies conducted over an extended period of time, this assumption may not be reasonable. This has lead to the development of stopover models within ecological applications, where individuals may enter and leave the population within the study period, so that the total population size is not constant throughout the study. Whenever the underlying assumptions are violated, the population estimates may become positively or negatively biased.

Summary

Estimating population sizes will continue to be an important aspect of many areas of the sciences and humanities. Capture–recapture methods are often used to obtain data that can be used to estimate the population size of interest. Understanding the limitations of the statistical models and associated assumptions that are made within the corresponding analyses will aid in the interpretation of the estimates obtained (and their use within, for example, social policy, etc.). Within any analysis, the population to be estimated needs to be clearly defined and appropriate sources used for the given population of interest. For example, suppose that the population of interest is the number of injecting drug users in a given area. Considering only sources that are dependent on such individuals also being prescribed or taking methadone leads to the population size being estimated relating to injecting drugs and methadone users (and not simply injecting drug users only). Understanding the data collection survey and collation of data between the different sources will provide further insight into the requirements of the subsequent statistical models used to analyze the data. Implementing careful study designs and standardized policies may help to minimize the necessary assumptions (and potential capture heterogeneities) and lead to improved estimation of the population size of interest.

Abstract

Populism is a concept applied to a wide range of political movements and actors across the globe. There is, at the same time, considerable confusion about the attributes and manifestation of populism, as well as its impact on democracy. This contribution identifies the defining elements of the populist ideology and discusses the varieties in which populism manifests itself, for instance as a component of certain party families. We finally discuss various normative interpretations of populism, and the tension between populism and liberal democratic values.

The Russian Narodniki movement of the 1860–70s is mostly seen as the first appearance of modern populism. This short-lived grassroots movement of intellectuals never achieved mass adherents but represented a radical articulation of the idea that wisdom resides with the common people and that socialism should be based on the traditional peasantry as its heartland (Taggart, 2000). American populism, beginning in the 1880s and continuing particularly in the South throughout the twentieth century, also referred to themes of moral decay, conspiracy, and betrayal of the ordinary people by the corrupt elite. The history of American populism could be portrayed as reactionary and a nativist movement of great 'democratic promise' (Goodwyn, 1976). In addition, Latin American populism of the mid-twentieth century has received much attention. The emphasis was on nation-building under a centralized and charismatic leadership (see Weyland, 2001; Roberts, 2006). From the 1980s, there is a resurgence throughout the world of movements and leaders that have been dubbed populist. These include, for instance Collor, Menem, Chavez, Obrador in Latin America; Le Pen, Haider, Wilders, Dewinter in Western Europe; Buchanan, Perot, Manning in the United States and Canada; Hanson in Australia; and Meciar, Milosevic, Lukashenko, Orbán in post-communist states. The populist label has thus been attached to a variety of political movements. It has been used as a term of approbation only by some movements themselves and mostly as a pejorative term by critics.

Populism: Mobilization, Leadership, Style, or Ideology?

The core idea of populism rests with the claim to represent or act in the name of the people, understood as the 'common people' and the 'silent majority.' Nevertheless, the main problem of defining populism is that conceptualizations encompass very different traits, while analysts apply the term to diverse phenomena. One approach suggests that populism is essentially a strategy of *political mobilization* using a typical style of political rhetoric (Kazin, 1995). It considers populism to be a tool for a leader to seek and exercise power. Populist parties and leaders appeal to the power of the common people to challenge the legitimacy of the current political establishment. A second approach focuses on populism as a *type of organization*. Populism presents itself not as an ordinary party characterized by different factions and an appeal to a specific section of society, but as a unified bloc or movement of the people. The movement is characterized by a politics of personality centered on a strong, personalized, even charismatic leader who is said to embody the will of the common people and who is able to speak on their behalf. The leader–mass linkage is direct, rather than mediated by organizations. As a result, populist framing is linked to a particular *style of communication* (Tarchi, 2002). Populism utilizes an antitheoretical rhetoric and anti-intellectual oratory to exploit feelings of resentment politically (Betz, 1994; Abts, 2012). Populists offer simplistic solutions to complex political problems in a very direct and demagogic language, appealing to the common sense of the people and denouncing the intellectualism of the established elites. Although charismatic leadership and simplistic language might be associated with populism, these action frames could, arguably, only be understood as expressions of an underlying populist ideology. However, populism needs to be understood as a *thin-centered ideology* because it does not provide a comprehensive vision of society (Mudde, 2004; Abts and Rummens, 2007; Stanley, 2008). It only gives a precise meaning and priority to certain key concepts of political discourse, thereby generating a particular ideological picture of parts of the political domain.

The Elements of the Populist Ideology

Populism is intrinsically "a thin-centered ideology which advocates the sovereign rule of the people as a homogeneous body" (Abts and Rummens, 2007: p. 409). Three elements of populist ideology are recurrently highlighted in the literature. First, it is argued that populism revolves around a central *antagonistic relationship between 'the people' and 'the elite.'* Populism is an "appeal to 'the people' against both the established structure of power and the dominant ideas and values of society" (Canovan, 1999: p. 3). The establishment is attacked for its alleged privileges, its corruption, and especially, for its lack of accountability

to the people. Elites are accused of representing only their own interests and of being alienated from the real interests, values, and opinions of the common man.

Secondly, populism tries to give power back to the people and restore *popular sovereignty*. Populists believe that politics should be based on the immediate expression of the general will of the people. They speak and behave as if "democracy meant the power of the people and only the power of the people" (Mény and Surel, 2002: p. 9). Populist ideology favors more direct forms of democracy, such as majority rule or referenda, which should replace current representative and intermediary institutional arrangements. Thereby, the will of the people is considered to be transparent and immediately accessible to those willing to listen to the *vox populi*. Thus, populism is wary of compromise and accommodation, and emphasizes the need for a politics of will and decision (Urbinati, 1998: pp. 116–118). As a consequence, there is no need for elaborate discussion or party politics, and populist movements and parties are often headed by charismatic leaders who can speak and act directly on behalf of the people. Populist democracy can be understood as an attempt to achieve an immediate identity of governed and governing. Populists claim to present and proclaim, not to represent, the essentialist will of the people. In this way, populism opts for the idea of popular sovereignty, if necessary, at the expense of constitutional guarantees.

Thirdly, the transparency of the will of the people is possible because populism conceptualizes the *people as a homogeneous unity* (Abts and Rummens, 2007). In populist ideology, 'the people' functions as a central signifier, which receives a fundamentally monolithic interpretation. The people are united and indivisible, fully formed, self-aware, and identifiable by the majority of numbers. Accordingly, the people are not seen as a heterogeneous collection of social groups and individual subjects with diverse values, needs, and opinions. On the basis of a supposed shared identity, the people are considered to form a collective body, which is capable of having a common will and a single interest and which is able to express this will and to take decisions (Canovan, 2002: p. 34). Populist ideology, however, only implies *that* the people constitute a homogeneous body, it does not say *what* this substantive identity should be. All actual populist movements need to supplement their thin-centered populist ideology with additional values and beliefs that give content to this substantive unity. Populism, then, cohabits with other, more comprehensive ideologies depending on the context and the values of the heartland to which it appeals. Paradigmatic possibilities here would be a leftist version of populism that identifies the people in socioeconomic terms as the working-class exploited by a bourgeois elite or a right-wing populist movement that refers to ethnonational characteristics to identify the people with the (ethnic) nation (see Mudde and Rovira Kaltwasser, 2013). The presumed unity of the people also implies that populism cultivates antagonistic relationships toward those who do not fit in and therefore threaten the homogeneity. Depending on the specific nature of the populist image of the people, this might include, for example, cultural and economic elites, foreigners, minorities, welfare recipients, or others. It can then be argued that populism is an inherently antipluralistic ideology.

Based on these three core elements, scholars present different, yet overlapping, descriptions. Mudde (2004: p. 543) defines populism as "an ideology that considers society ultimately separated into two homogeneous and antagonistic groups, 'the pure people' versus 'the corrupt elite,' and argues that politics should be an expression of the *volonté générale* of the people." Albertazzi and McDonnell (2008: p. 3), on the other hand, conceptualize populism as "an ideology which pits a virtuous and homogeneous people against a set of elites and dangerous 'others' who are together depicted as depriving (or attempting to deprive) the sovereign people of their rights, values, prosperity, identity and voice."

Confronted with a great number and diversity of both movements and (ideological) traits it seems that populism occurs in various forms (e.g., style, strategy, and core ideological attribute), and is not confined to one specific type of political actor. The diversity of populist movements is accommodated by different typologies of populism – types differentiated in terms of traits in the core definition, which they lack. In their groundbreaking edited volume on populism, Ionescu and Gellner (1969) already observed that populism was used to refer to actors from a wide-ranging set of political ideologies. Later, Canovan (1981: p. 133) argued that it is not possible to unite different populist movements "into a single political phenomenon with a single ideology, program or socioeconomic base." Notwithstanding the diversity among populist parties, several patterns can be distinguished. Populist leaders in Latin America, for example, tend to be characterized by a socioeconomically left position, whereas populism in Europe is often associated with the radical right (Mudde and Rovira Kaltwasser, 2013). In the United States, in turn, populism is often seen as an intrinsic feature of politics, in view of the more general wariness of big government and the Washington elite (see Ware, 2002). More recently, the term has often been associated with the culturally conservative and anti-statist Tea Party. In organizational terms, populism in Europe is predominantly seen as a feature of political parties rather than individuals – even though many of those parties are characterized by centralized leadership and a strong figurehead. Irrespective of the general tendency of populism to cohabit with the xenophobic right, populism in Europe has also been associated with other 'party families.'

Populism in Party Families

Mudde (2007) has treated populism as a core element of the populist radical right (PRR), but also identified two other types of populist parties: neoliberal populists and social populists (see also March, 2011). Parties from the latter two families are mainly concerned with socioeconomic themes – promoting free-market economics and welfare protectionism, respectively – while PRR parties are, besides their populism, primarily characterized by their nativism and authoritarianism. Thus, even though it would not be accurate to speak of a populist 'party family,' because populist parties can come in various ideological shapes and guises, several party families can be distinguished for which populism is a defining characteristic.

Again, while there have been prominent examples of neoliberal populist parties (e.g., those of Silvio Berlusconi in Italy and Pim Fortuyn in the Netherlands) and social populists

(such as Die Linke in Germany and Sinn Fein in the Republic of Ireland), the majority of the cases of populism in Europe appear to fall within the PRR category. In Western Europe, these parties are for instance characterized by their hostility against immigration and emphasis on the need for foreigners to adapt to the nation's customs. Several such parties have been around for quite a long time: the Front National (FN) in France was founded in 1972, the Vlaams Belang (VB, previously Flemish Block) in 1978. Other parties with a longer history have transformed themselves into successful PRR parties more recently – the Austrian Freedom Party (FPÖ) and the Swiss People's Party being prime examples. In post-communist countries in Central and Eastern Europe, where immigration levels have been low or even negative, populist radical right parties have typically identified ethnic minorities – and in some countries the Roma population in particular – as the nonnative elements. Examples include parties such as Jobbik in Hungary, the Greater Romania Party (PRM), and the Slovak National Party (SNS).

It must be noted that populism is not necessarily a phenomenon confined to certain parties only. In Europe, too, populism can take the form of a more fleeting rhetorical device used to blame electoral competitors for having lost touch with the 'ordinary people.' In post-communist countries, where political trust tends to be low and public sector corruption is often a salient electoral theme, many (newly established) political parties have voiced populist antiestablishment rhetoric (Van Kessel, 2014). The term populism has also regularly been used to describe large mainstream parties such as the Hungarian FIDESZ and the Polish Law and Justice (PiS).

The difficulty in pinpointing exactly which actors are populist or not has added to the concept's unsystematic use and the more general confusion surrounding the term. Another problem of 'populism' is that the term is used rather randomly as a term of abuse and that populism is, without much substantiation, often automatically treated as a phenomenon that threatens the quality of democracy.

Populism and Democracy

Populism is regularly applied as a synonym for demagoguery, simplistic solutions, or opportunism (e.g., Mudde, 2004; Taggart, 2000). Especially in the vernacular sphere, the term is often used pejoratively to refer to vote-winning policy proposals, attempts to pander to public opinion, or anti-immigration attitudes (Bale et al., 2011). The academic debate about the concept may be more sophisticated, but also in scholarly literature, populism is frequently seen as a negative phenomenon. Betz (1994: p. 4), for instance, sees populism as a means of political opportunism that is unscrupulous and exploitative of the anxieties of the electorate. Others view populism's support for unmediated popular sovereignty as a threat to liberal democratic 'checks and balances' and the protection of minorities. Abts and Rummens (2007: p. 4), for instance, argued that populism is inherently incompatible with democracy; populism's conception of the people as a homogeneous body is fictional and "generates a logic which disregards the idea of otherness at the heart of democracy and aims at the suppression of diversity within society."

A more optimistic view is that populism is an indicator of the health of representative democracy. Although not denying the risks of populist politics, some scholars argue that populism emerges when the political elite loses track of the popular will, or when the 'constitutional' or 'liberal,' as opposed to the 'democratic' or 'popular' pillar of democracy, is seen to become too dominant. Taggart (2002: p. 63), for instance, argued that populism acts as a 'bellwether' for the health of representative politics. Mény and Surel (2002: p. 17) have described populism as "a warning signal about the defects, limits and weaknesses of representative systems," and argue that "in spite of its often unpleasant tones, it may constitute an effective reminder that democracy is not a given, but is instead a constant enterprise of adjustment to the changing needs and values of society." Canovan (1999: p. 11) speaks about the tension between the 'pragmatic' and 'redemptive' faces of democracy and argued that "When too great a gap opens up between haloed democracy and the grubby business of politics, populists tend to move on to the vacant territory, promising in place of the dirty world of party manoeuvring the shining ideal of democracy renewed. Even from the point of view of pragmatic politics, the vital practices of contestation and accountability grow weak without the energy provided by democracy's inspirational, mobilizing, redemptive side."

Still, populism is seldom seen as an unequivocally good thing. Not many scholars appear to subscribe to Laclau's (2005: p. 48) argument that populism and democracy are essentially interchangeable terms and that "the end of populism coincides with the end of politics." Panizza (2005: p. 30) instead described populism as a 'mirror in which democracy can contemplate itself,' but argued that 'populism is neither the highest form of democracy nor its enemy.' In the same volume, Arditi (2005) argued that populism can appear in three possible modes: populism as a mode of representation, as a symptom, or as an underside. The first mode is compatible with liberal-democratic politics, the second presents a disturbance of democracy, whereas the latter entails an actual interruption of democracy. Pasquino (2008: p. 28), in turn, argued that the appearance of populism is often a sign of a poorly functioning democratic regime, but that populism, for instance due to its unrealizable promises, has a negative impact on the democratic framework itself.

An edited volume by Mudde and Rovira Kaltwasser (2012) attempted to test empirically the consequences of populism in several countries in Europe and the Americas. Based on the various case studies, the editors concluded that populism can be a corrective as well as a threat to democracy. Populist actors can, for instance, place issues on the agenda which have been ignored by the political establishment and give voice to excluded sections of society. Yet especially in unconsolidated democracies, populism can also undermine liberal democratic institutions in view of its monist conception of society and disdain for 'checks and balances.'

As a consequence, an obvious question is how established political actors could react to emerging populism. A quick glance reveals that Western Europe is divided about how to deal with PRR parties. In Italy, Austria, Denmark, and the Netherlands a rather open and accommodating approach prevails whereby populist challengers are treated as ordinary political opponents and forms of cooperation remain possible.

In other countries, such as France and Belgium, institutional and political actors pursue a much more repressive and antagonistic approach whereby the populist parties are delegitimized and treated as genuine enemies of the democratic system (Eatwell and Mudde, 2004). Consequently, the public debate is largely determined by different stances toward the well-known dilemma of 'tolerance for the intolerant.' On the one hand, the *procedural view* conceives of democracy as a set of procedures organizing the struggle for power. In the electoral marketplace, all opinions and parties are tolerated as long as they follow the procedural rules. As a result, freedom of expression and association is almost unlimited. The adherents of the procedural view propose to treat populist parties as legitimate opponents in the political struggle, while it would be inappropriate to challenge political opponents with repressive rules of exclusion. On the other hand, the *substantive view* advocates a more repressive stance toward populism, in case it leads to extremism. Democratic procedures are not an end in themselves but only the means for realizing and protecting a set of substantive democratic values and rights. Consequently, all political parties are required to underwrite the fundamental values of freedom, equality, respect, and tolerance. As far as populists threaten these values, the tolerance for the intolerant may be limited. In this sense, repressive measures like a cordon sanitaire, which aim to obstruct extremist parties, are not allowed but actually required (Capoccia, 2007: pp. 55–67). Instead, Rummens and Abts (2010) propose a concentric containment policy for dealing with populist parties in trying to overcome the traditional opposition between procedural and substantive views of democracy. On the procedural side, this policy emphasizes the importance of tracking all the relevant concerns of citizens in the public sphere, whereas, on the substantive side, it stresses the need for an adequate filtering which guarantees the compatibility of actual policies with the core values of liberty and equality. Their proposed twofold requirement of tracking and filtering translates into a guideline of decreasing tolerance toward populists as they approach the centers of formal decision-making power. The resulting containment policy listens to populist voters, but puts simultaneously unremitting civilizing pressure on populist parties themselves.

This article is a revision of the previous edition article by N.M. Malamuth, volume 17, pp. 11816–11821, © 2001, Elsevier Ltd.

Abstract

The following is a review of pornography consumption patterns and effects of pornography on attitudes, cognitions, and behaviors. The review shows that pornography is widely circulated and used; predominately nonviolent pornography is used; main media outlets for consumption are the Internet, videos/DVDs, television, and magazines; and most often pornography is watched at home, either alone or with a regular sexual partner. Further, although causality cannot be conclusively established, an increasing amount of diverse empirical evidence suggests a variety of associations between pornography and certain cognitions, attitudes, and behaviors for a subgroup of users. This implies that possible links between pornography and certain cognitions, attitudes, and behaviors are moderated by individual and contextual differences.

Introduction

The topic of pornography has been discussed from many vantage points and is often hotly debated by scholars and researchers. Some have focused on the functions and effects of pornographic mass media as they pertain to understanding the impact of pornography on individual consumers, for example, in the realms of fantasy, sex education, esthetic/artistic expression, the sex life, and reproduction. Yet others have approached the topic at a broader level, exploring such topics as the relevance of pornography to male–female relationships, family and group relations, social institutions, the role of government regulation, and social change.

Traditionally, opponents of pornography have claimed that pornography may have damaging effects on beliefs, morals, values, attitudes, and behaviors, and they hold pornography responsible for a variety of adverse effects, including wrecking marriages, negatively changing men's perceptions of women and women's perceptions of themselves, sexual addiction, unhealthy attitudes, and problematic (sexual) behaviors. On the contrary, proponents of pornography have claimed that little or no such effects of pornography consumption are evident. Rather, pornography may benefit the individual by enhancing the sex life, contributing to knowledge about sex, providing a recreational sexual outlet, buffering against sexual assaults, or helping to assess or cure common sexological dysfunctions.

It is beyond the scope of this article to consider all of these diverse approaches to the topic of pornography. Instead, the focus here may be described as a 'social science-centered' approach revolving around two central questions: First, what are the findings on pornography consumption patterns? Second, what are the findings of effects of pornography on attitudes, cognitions, sexual behaviors, and sexually aggressive behaviors?

Given the controversial nature of pornography, it is important to stress that the following review should not be seen as an attack on or defense of pornography but as an attempt to synthesize current empirical literature on pornography.

Defining Pornography

Originally, the term *pornography* referred to the writings about or depictions of harlots or prostitutes. The term derives from the Greek word *pornographos*, which again derives from the Greek words *pórne*, meaning 'whore,' and *graphein*, meaning 'to write.' Thus, the term originally referred to 'writings on whores.'

In terms of legal definitions, the terms *pornography* and *obscenity* need to be distinguished. Obscenity refers to pornographic content that has been judged by the legal system to be illegal. In the United States, most states use the 1973 Supreme Court decision in *Miller vs. California* as the legal definition of *obscene*. To be judged obscene under this case the material must satisfy three conditions: (1) The average person, applying contemporary community standards, would find that the work, taken as a whole, appeals to the prurient interest; (2) the work depicts sexual conduct in a patently offensive way; and (3) the work, taken as a whole, lacks serious literary, artistic, political, or scientific value.

According to Diamond (2009) the most common definition of pornography used by researchers today is: "media basically construed as intended to entertain or arouse erotic desire" (p. 304). Nonviolent pornography may be defined as sexually explicit materials without any overt coercive content, but which may sometimes imply acts of submission and/or coercion by the positioning of the models, use of props, or display of unequal power relationships. Violent pornography may be defined as sexually explicit materials in which nonconsensual, coercive, and/or violent sexual relations are explicitly portrayed (see also Hald et al., 2010). However, as elaborated upon in the following section, some ambiguity exists in how to define 'violent pornography.'

Pornography Consumption Patterns

Prevalence of Pornography Consumption

Some of the most consistent findings in the area of pornography research are the relatively high consumption rates especially among men and the large gender differences in

consumption patterns. Following are summaries of such and related findings.

Consumption rates

With few exceptions, international studies have reported consumption rates in the range of 50–99% amongst men and 30–86% amongst women. However, these rates have been found to be heavily influenced by sample characteristics (e.g., age), time period assessed (e.g., pornography consumption in the past six months, year, ever), sexual experience, definition of pornography, and study methodology and design.

Gender differences

Compared to women, men have been found to use pornography more frequently, spend more time on pornography consumption, be exposed to pornography at a younger age, and use pornography more often during masturbation. Further, compared to women, men prefer pornography with many different actors as compared to pornography with the same actors performing different acts, are more attracted to both a wider range of hardcore pornography and hardcore pornography devoid of relationship context and emotional attachments, and are generally, more sexually aroused by pornography (Hald and Malamuth, 2008).

Frequency of exposure

According to Edelman (2009), based on a 2008 monitoring of Internet usage patterns, 36% of users visited at least one adult entertainment website per month. Among these 36%, the average number of visits to adult websites was 7.7 times a month with an average visit lasting 11.6 minutes. It has been estimated that around 25% of all Internet search engine requests are for pornography, and some of the most popular search engine request words are sexually related.

Age of first exposure

Age at first pornographic exposure varies from culture to culture, but most findings suggest that first nonaccidental exposure on average happens between the ages of 11 and 15 with men being exposed at a significantly younger age than women.

Pornography Consumption Outlets

Financially, the porn industry has been 'big business' with the largest companies being listed on stock exchanges and many other large companies (e.g., hotel chains, cable networks, etc.) gaining much revenue from such media content. In a 2006 estimate, the AVN Media Network, an adult entertainment trade organization, estimated the total retail sales of pornography to approximately US$ 13 billion. Up until the 1990s the dominant media outlets for pornography consumption were magazines, videos/DVDs, and television. However, this changed in the wake of the Internet and smartphone revolution where high-speed connections increasingly allowed for easy, cheap, and convenient access to all types of pornography (Edelman, 2009). Today, the predominant media outlets of pornography consumption are the Internet, videos/DVDs, television, and magazines.

Types of and Reasons for Pornography Consumption

Increased recent concerns regarding the consumption of pornography have focused on the easy and inexpensive access to all types of pornography. This especially concerns the use of violent pornography or more atypical kinds. Unfortunately, systematic longitudinal studies of dominant types/themes of consumption of pornography over the past several decades are not available.

Content of pornography

Most of the pornography consumed today is primarily of a nonviolent nature according to the definitions described herein. The dominant themes of consumption include: vaginal-, anal-, oral-, and group sex. In total, approximately 10–15 % of users prefer same-gender, violent/coercive, fetish, Bondage & Domination (B&D), or Sadomasochism & masochism (S&M) pornography (Hald et al., in press).

However, potential ambiguity in how to define 'violent pornography' is highlighted by a recent content analysis of the leading 'adult' films (Bridges et al., 2010). This study content analyzed a randomly selected representative sample of 50 adult film videos from the 2004–05 list of best-selling adult film videos. The authors noted the problem of applying the term *violence* and chose instead to focus on the frequency of 'aggression' in adult films, including a wide range of physical acts to define physical aggression:

> (a) pushing or shoving; (b) biting; (c) pinching; (d) pulling hair; (e) spanking; (f) open-hand slapping; (g) gagging (defined as when an object or body part, e.g., penis, hand, or sex toy, is inserted into a character's mouth, visibly obstructing breathing); (h) choking (when one character visibly places his or her hands around another character's throat with applied pressure); (i) threatening with weapon; (j) kicking; (k) closed fist punching; (l) bondage or confining; (m) using weapons; and (n) torturing, mutilating, or attempting murder (p. 1075).

Also coded separately in this content analytic study were verbally aggressive acts that included (1) name calling or insulting and (2) threatening physical harm. In terms of agreement among coders, trained coders reached very high levels of agreement regarding the various types of aggression portrayed. The findings indicated that using this highly inclusive definition of physical aggression, the clear majority of adult videos included some forms of aggression. For instance, over 75% of the scenes included portrayals of spanking and over 50% of gagging. Choking occurred in about 28% of the scenes.

However, the portrayal of what may be described as violence (according to widely accepted social scientific definitions of this concept) in this sexual content was actually very rare: none of the scenes portrayed the use of threat with a weapon, hitting with a closed fist, torture, or mutilation. Using coercive language occurred in only 1.6% of the scenes. Thus, at least in 'mainstream' commercially released pornography, it would appear that violent pornography is rare. Nevertheless, earlier trends, documented some time ago, appear to have shown considerable increases in the accessibility of violent pornography in recent years, fueled by the Internet revolution (Gaddam and Ogas, 2011).

Reasons for Consumption

A variety of reasons for consuming pornography are given by consumers, with the most prevalent being: involuntary/chance exposure (e.g., spam, pop-ups), for entertainment/fun, curiosity, sexual learning, mood management, out of habit, to build and maintain relationships, for fun, to enhance sexual fantasies/the sex life, and as a prelude to or intensifier in autoerotic activities, or sexual intercourse (Emmers-Sommer and Burns, 2005).

Situational and Interpersonal Characteristics of Pornography Consumption

Few quantitative scientific studies have examined preferences in, and situational and interpersonal characteristics of pornography consumption. For both men and women, these studies have found that the main place of use is 'home,' and that the interpersonal context of use is either 'alone' or with a 'regular sexual partner' (e.g., Hald, 2006). Although teenagers in particular also report watching pornography with friends, this is not common fare. Using both American and Scandinavian samples research finds that female users are significantly more likely than male users to report watching pornography with a sexual or dating partner, whereas male users are significantly more likely than female users to report watching pornography alone (Hald et al., in press).

Summary: Patterns of Pornography Consumption

Pornography is widely circulated and used. In general, many gender differences in pornography consumption patterns have been consistently demonstrated. Although also used by women, pornography consumption amongst men can be conceptualized as a cornerstone of their autoerotic sexuality.

Most of the pornography consumed today is primarily of a nonviolent nature. The predominant themes of preference include vaginal-, oral-, anal-, and group sex, with only a smaller group of users preferring themes such as violent/coercive, fetish, B&D, or S&M pornography. Presently, the dominant media outlets are the Internet, videos/DVD, television, and magazines. Pornography is most often watched at home, either alone or with a regular sexual partner. Main reasons for watching pornography include involuntary/chance exposure, entertainment/fun, curiosity, sexual learning, to enhance sexual fantasies/the sex life, and as a prelude to or intensifier in autoerotic activities or sexual intercourse.

Effects of Pornography

Effects of Pornography on Attitudes

In the controversy about effects of exposure to pornography, attitudes have long held a central and decisive role. The widely accepted conceptualization of 'attitudes' usually incorporates three components, including affective responses, cognitive evaluations, and behavioral predispositions toward an entity (see also Hald et al., 2010). Predominately, attitudes supporting violence (ASV) against women (including rape supportive attitudes and beliefs), sexist attitudes, sexually permissive attitudes, and attitudes toward pornography have been targeted in pornography research.

Attitudes Supporting Violence against Women

ASV have been conceptualized as (1) affective responses to acts such as rape, other types of sexual aggression, and partner violence, (2) evaluative cognitions, and (3) behavioral predispositions or attractions toward such aggressive acts (Malamuth et al., 2012). Consequently, ASV also incorporates rape supportive attitudes and rape myth acceptance (see also Allen et al., 1995b).

Generally, data from a wide variety of experimental and correlational studies have converged to show that for some individuals pornography consumption may increase ASV (Allen et al., 1995a; Hald et al., in press). In a recent meta-analysis on the relationship between pornography consumption and ASV in nonexperimental studies, Hald et al. (2010) found a significant association between pornography consumption and ASV, with a significantly stronger effect for violent than nonviolent pornography. Furthermore, Hald et al. (2010) found heterogeneity among the included studies to a degree indicative of moderating variables, although the literature encompassed in this meta-analysis did not enable the authors to identify the basis for such moderation. However, another study by Malamuth et al. (2012) using a large representative sample of American men made this possible. It was found that the significant association between pornography consumption and ASV was moderated by individual differences in risk of sexual aggression, such that consumers at the highest risk level of sexual aggression who reported the most frequent use of pornography also held the highest level of ASV. These results from nonexperimental studies converge with results from experimental studies. For example, in a meta-analysis on pornography and ASV in experimental studies, Allen et al. (1995a) reported a significant effect of pornography consumption on ASV with a stronger effect for violent than for nonviolent pornography.

Sexist Attitudes

Sexism has been defined as a form of negative attitude toward women (or men) including hostility, negative prejudices, and stereotypes (Glick and Fiske, 1996). Sexist attitudes have been linked to a number of adverse effects. These include discrimination against women, gender rigidity, hostility, and anger toward women, greater self-reported likelihood of using violence in relationships with women, acceptance of rape myths, and the commission of real-life sexual aggression, including rape (Hald et al., in press). Studies on the association between pornography and sexist attitudes present an ambiguous and inconsistent picture. Thus, a number of previous survey and experimental studies fail to demonstrate significant associations between pornography and sexism or find only weak positive associations or even negative associations between pornography and sexism. This may be due to the lack of distinction between differing kinds of sexist attitudes (see also Glick and Fiske, 1996) or to the overall scientific quality of some of these studies, which has been seriously questioned (Malamuth et al., 2000), or because

many of these studies fail to consider individual differences as potentially important effect moderators. In view of the findings from other areas of the pornography effects research that specifically highlight the importance of moderators, this seems a critical shortcoming.

Other research studies, among them prospective and longitudinal studies, report that pornography consumption of various kinds increases 'notions of women as sex objects' and is associated with significantly stronger gender stereotypic attitudes and cognitions in sexually coercive males as compared to both normal controls and young males with a conduct disorder. Further, studies report that men who habitually consume high amounts of Internet pornography are more likely to view women in stereotypical gender roles, perceive a world inhabited by masculine men, and report the highest level of self-perceived masculine personality characteristics. Further, for both males and females, early exposure to sexually explicit media has been found to predict less progressive gender role attitudes, and, for males only, greater sexual harassment perpetration 2 years later (Brown and L'Engle, 2009).

Sexually Permissive Attitudes

Exposure to pornography has been shown to be significantly associated with sexually permissive attitudes, with stronger associations for Internet pornography than for more traditional types of pornography consumption (Kingston et al., 2009). For example, using both American, Dutch, Scandinavian, and Taiwanese samples of youths and young adults, it has been shown that more frequent exposure to sexually explicit Internet material is associated with more positive attitudes toward uncommitted sexual exploration, for example, sexual relations with casual partners/friends or with sexual partners in one-night stands, sexually permissive attitudes, positive attitudes toward sex, sexually permissive attitudes, and an expansive sexuality including more positive attitudes toward oral and anal sex as appealing. Further, in a large-scale longitudinal study of American youths, Brown and L'Engle (2009) found both large significant positive associations between pornography consumption and permissive personal sexual norms at baseline, and that, among men, increased exposure to pornography at baseline predicted more permissive personal sexual norms 2 years later, even after controlling for baseline sexual norms, demographic variables, and sensation seeking.

Attitudes toward Pornography

One of the best documented effects of pornography exposure is that repeated exposure results in more favorable attitudes toward pornography (ATP). American, Danish, Finnish, Italian, Norwegian, and Swedish studies all indicate gender differences in ATP (see also Hald et al., in press). In these studies, it was found that women more than men favor restrictions on pornography and are more likely to describe pornography as dull, not exciting, or repulsive. Further, compared to women, men express more positive ATP and are more likely to view pornography as a means of sexual enhancement.

Summary: Attitudes

Using a variety of subject samples, study designs, and cross-cultural research, significant positive associations between pornography consumption and both ASV, sexually permissive attitudes, and attitudes toward pornography have consistently been demonstrated. Research including individual differences has revealed the critical importance of individual differences in the pornography-attitudinal relationship. For the relationship between pornography consumption and sexist attitudes, findings are more conflicting and inconclusive.

Effects of Pornography on Cognitions

Abnormalities in the perceptual-, memory-, or information-processing systems may lead to maladaptive, offense supportive cognitions and problematic interpretations of stimuli and social encounters (see also Ward and Beech, 2006). Further, these systems may work as preattentive filters biasing the intake and processing of information and prime offense supportive cognitions (Ward and Beech, 2006). In turn, offense supportive cognitions may evoke emotional, attitudinal, and behavioral responses, increasing the probability of sexually aggressive behaviors. Pornography exposure may affect these cognition-related systems.

Cognitively, pornography may prime, maintain, and reinforce offense supportive cognitions, for example, that women are constantly receptive to men's needs, deceptive, or treacherous (Ward and Beech, 2006). When primed repeatedly, such cognitions may result in the chronic accessibility of attitudes that reduce the responsibility of men who commit acts of aggression against women and generally reinforce the acceptance of dominating, controlling, and perhaps even violent acts of aggression against women.

Individual differences moderation found in previous research (e.g., Malamuth et al., 2012) suggests that such priming, maintenance, and reinforcement by pornography may be particularly probable for men classified at high risk of sexual aggression (see also Malamuth et al., 2000; Ward and Beech, 2006) as these men often already hold hostile/power schemas associated with women and sexuality and view women dichotomously as either 'whores' or 'madonnas.'

Thus, the availability and accessibility of offense supportive schemas similar to that of (some) pornography may already be in place for, as well as perceptually and emotionally attended to, by this group of men. In keeping with these findings, exposure to pornography may not activate similar schemas in men classified at low risk of sexual aggression because of the low occurrence or accessibility of such schemas among this group of men.

These findings may also help explain the interaction of pornography and individual differences in the development of stronger offense supportive schemas supporting violence against women, as men at greater risk for sexual aggression are more likely to choose to expose themselves to violent or similar forms of pornography (Malamuth et al., 2012).

Summary: Cognitions

Associations between pornography consumption and certain (offense supportive) cognitions have been hypothesized, as

have some of the possible mechanisms by which such associations may occur. However, studies testing these hypotheses and probable mediating mechanisms are still sparse. Further, the direction of causality between pornography consumption and cognitions is yet to be established.

Effects of Pornography on Behavior

Perhaps the most critical questions in pornography effects research have been whether, if, and how pornography consumption influences behaviors. Traditionally, two groups of behaviors have mainly been studied, namely sexual behaviors and sexually aggressive behaviors.

Sexual Behaviors

Using a variety of cross-cultural samples, methodology, and designs research has generally and with great consistency demonstrated associations between pornography consumption and sexual behaviors. For example, significant positive relationships have been found between pornography consumption and frequency of masturbation, varied sexual experiences, precoital behaviors, ever to have sold sex, lower age at first intercourse, number of sexual partners during the past year, number of overall and casual sexual intercourse partners, having multiple lifetime partners, having engaged in oral, anal, or group sex, not to have used contraception during the last intercourse, and to having had a sexually transmitted infection (Hald et al., 2013).

Even though pornography consumption has been consistently found to be associated with a diversity of sexual behaviors, this is not evidence of causal links between pornography consumption and sexual behaviors. As proposed by Hald et al. (2013) and others, associations between pornography consumption and sexual behaviors may be spurious, confounded, and/or (better) accounted for by third factors, such as individual differences in personality or sexual background variables. Indeed, Hald et al. (2013), using a large Dutch youth sample, found the added significant prediction values of pornography consumption on sexual behaviors (and vice versa) to be limited when controlling for the combined influence of a comprehensive array of factors previously identified as important influences of the pornography consumption-sexual behavior relationships, for example, (sexual) sensation seeking.

Sexually Aggressive Behavior

Sexually aggressive behavioral outcomes include verbal manipulation, taking sexual advantage of an intoxicated person, or physically forcing someone into sexual activities against their will (see also Hald et al., 2013). Longitudinal studies, reviews, and meta-analyses of existing literature have all shown positive associations between pornography consumption and sexually aggressive behaviors (e.g., Allen et al., 1995b; Kingston et al., 2009; Malamuth et al., 2000). However, these associations have also been shown to be moderated by various individual differences (see also Kingston et al., 2009). Such research suggests that once an individual possesses certain other key risk factors, then and only then does pornography consumption add significantly to the confluence or interactive combination of these key risk factors in the prediction of sexual aggression. This line of thinking is evident in leading integrative or multimodal models of sexual aggression, such as the Confluence Model of Sexual Aggression (e.g., Malamuth et al., 2000) and the Three Path Model (e.g., Knight and Sims-Knight, 2011).

In known groups of sexual offenders, pornography use has been assessed in terms of frequency and type of pornography used. However, much of this research has been equivocal and remains inconclusive (see also Kingston et al., 2008). In contrast, and in keeping with the models described before, a relatively recent study examining the unique contribution of pornography consumption to the longitudinal prediction of criminal recidivism in a large sample of child molesters found that, after controlling for general and specific risk factors for sexual aggression, pornography still added significantly to the prediction of recidivism (Kingston et al., 2008). Further, this study also indicated that frequency of pornography consumption was primarily a risk factor for higher-risk offenders.

Summary: Behavior

Across studies, cultures, and population samples, associations between pornography consumption and a diversity of sexually related behaviors have been consistently demonstrated. In the area of sexually aggressive behaviors, the research has indicated that it is the confluence or interactive combination of general antisocial factors, contextual factors, and factors specific to sexual aggression, including pornography use, that have the strongest predictive power of sexually aggressive behaviors. Consequently, potential effects of pornography on sexually aggressive outcomes are best conceptualized and understood within comprehensive integrative and empirically validated theoretical frameworks.

Further, research has demonstrated that increased risk of sexually aggressive outcomes on the basis of pornography consumption may only occur for a small subgroup of users, namely those already at relatively high risk of committing sexual aggression and amongst the most frequent pornography consumers. Although findings of pornography-behavioral links are fairly consistent throughout the literature this does not imply causality, nor that this relationship may not be (better) accounted for by third factors.

Beneficial Effects of Pornography

Predominately, pornography effect research has focused on adverse effects of pornography (consumption). However, especially in recent years, increasing focus has been on possible positive or beneficial effects of pornography. Thus, empirically, pornography consumption has been shown to benefit the individual by enhancing the sex life, contributing to knowledge about sex, providing a recreational sexual outlet, expanding sexual horizons through normalization of sexual behaviors, facilitating a willingness to explore new sexual behaviors and sexual relationships through empowerment, helping to assess or cure common sexological dysfunctions, assisting in medical settings in which semen is collected for reproductive purposes,

and improving the quality of life in general (Hald and Malamuth, 2008).

Many of the findings cited herein rely on self-reported and self-perceived effects of pornography. While proponents of pornography would argue that the individuals themselves are in the best position to judge such effects, and that results from studies such as the above should therefore be taken at face value, critics of pornography have described the gradual greater recognition of pornography as beneficial, and de facto, positive as one of the most insidious effects of consumption (see also Hald and Malamuth, 2008).

Conclusions

Pornography research has often been influenced by ideological/political perspectives with vested interests in particular conclusions. This may have led to framing of research questions and design of some studies in ways that encourage simple conclusions, while not readily accommodating more nuanced conclusions. Nevertheless, research in this area has progressed considerably. In future work, it is essential not to use an 'either–or' perspective in which research is cast simply into questions such as whether pornography exposure is generally harmful or not. As suggested in the research summarized here, differing conclusions may result depending on a variety of factors such as the cultural milieu, the individual's background and risk profile, the particular content of the stimuli, the type of responses focused on, the content of exposure, the consumer's environmental circumstances, and the way 'harm' is defined. Some may wish for a 'one-handed' set of conclusions, but the research more accurately justifies a 'multihanded' perspective that reveals the richness and complexity of the issues related to the study of pornography.

Abstract

Positivism is the name of a social and intellectual movement that tried to learn from the mistakes of the Enlightenment project that eventuated, first, in the Reign of Terror following the French Revolution of 1789, and second, in the irrationalism of the Weimar Republic following Germany's defeat in World War I. While it has been customary to distinguish between the quasipolitical movement called 'positivism' originated by Auguste Comte in the 1830s and the more strictly philosophical movement called 'logical positivism' associated with the Vienna Circle of the 1930s, both shared a common sensibility, namely, that the unchecked exercise of reason can have disastrous practical consequences. Thus, both held that reason needs 'foundations' to structure its subsequent development so as not to fall prey to a self-destructive scepticism. In this respect, positivism incorporates a heretofore absent empiricist dimension to the risk-averse orientation to the world historically associated with Platonism.

Positivism is the name of a social and intellectual movement that tried to learn from the mistakes of the Enlightenment project that eventuated, first, in the Reign of Terror following the French Revolution of 1789, and second, in the irrationalism of the Weimar Republic following Germany's defeat in World War I. While it has been customary to distinguish between the quasipolitical movement called 'positivism' originated by Auguste Comte in the 1830s and the more strictly philosophical movement called 'logical positivism' associated with the Vienna Circle of the 1930s, both shared a common sensibility, namely, that the unchecked exercise of reason can have disastrous practical consequences. Thus, both held that reason needs 'foundations' to structure its subsequent development so as not to fall prey to a self-destructive scepticism. In this respect, positivism incorporates a heretofore absent empiricist dimension to the risk-averse orientation to the world historically associated with Platonism.

Positivism's Platonic Political Roots

In terms of Western intellectual history, positivism inflects Plato's original philosophical motivation through a secularized version of the Christian salvation story, in which Newton functions as the Christ figure. This captures both the spirit of Auguste Comte's original project and its residual effects in twentieth century logical positivism, which dropped the overt historicism of Comte's project, while retaining the fixation on Newton as the model for what it means to express oneself scientifically and a vague belief that greater scientific knowledge will deliver salvation. Indeed, positivism's core conceptual problem has been to define a scientific vanguard capable of both offering guidance to the unenlightened and itself changing in light of further evidence and reflection. Its Platonic roots are worth recalling.

Plato was affected deeply by the volatile political environment created by the public dialectical encounters of Socrates and the other Sophists who mentored the leaders of his Athenian youth. Thus, after the fall of Athens, Plato was keen to restrict the dialectic to a cloistered setting, only to be unleashed to the larger society once initiates were sufficiently secure in their own knowledge and judgement that they would not be unduly swayed by popular demands. Where Plato had hoped to produce implacable philosopher-kings who would rule as absolute monarchs, positivists typically have envisaged a more differentiated but no less authoritative (authoritarian?) rule by experts, each an oligarch over their domain of knowledge. In this respect, positivism is bureaucracy's philosophical fellow traveler.

Not surprisingly, positivism's relationship to democracy has been chequered. Like Plato, positivists have feared protracted public disagreement most of all and hence have tended to demonize it as 'irrational' and 'noncognitive.' Their image of 'plural' authority presumes nonoverlapping competences, such that legislative questions are reduced to judicial ones concerning the expertise to which one should defer. This is in sharp contrast to most republican conceptions of democracy, which base representation on interest groups, each invested with a competence appropriate to the promotion of its interests but typically about matters in which other interest groups might also have competence. Since matters of public policy typically affect several such groups at once, collective decisions do not turn on identifying the right group whose judgement should hold sway. Rather, it is expected that public debate will issue in a solution that transcends all the groups' starting points but nevertheless manages to serve their respective interests.

Thus, there is a fundamental ambiguity in positivism's appeal to organized reason, or 'science,' in the public sphere. Sometimes this ambiguity is finessed by saying that positivists regard science as the main source of political unity. At the very least, this implies that it is in the interest of all members of society to pursue their ends by scientific means, as that may enable them to economize on effort and hence allow more time for the fruits of their labour to be enjoyed. Ernst Mach (discussed in Section. Antithesis: Machian Positivism) comes closest to defending this position in its pure form. It fits comfortably with the libertarian idea that democratic regimes should enable maximum self-empowerment.

However, many positivists have drawn a further conclusion that can thwart this libertarian impulse. From Comte onward, it has been common to argue that science can unify the polity by resolving, containing, or circumventing social conflict. Here a well-established procedure or a decisive set of facts is supposed to replace more 'primitive' and volatile forms of conflict resolution such as warfare and sometimes even open debate – all of which supposedly compromise the integrity of opposing viewpoints in the spirit of expedience. Accordingly, a scientific politics should not merely satisfy the parties concerned: it should arrive at the 'correct' solution.

To be sure, even this mentality admits of a democratic interpretation, as positivist social researchers have been in the forefront of presenting 'data' from parties whose voices are unlikely to be heard in an open assembly. Typically, this has occurred in surveys designed to represent the full empirical range of a target population. Nevertheless, the question remains of exactly who reaps the political benefits of these newly articulated voices: the people under investigation, the investigators themselves, or the investigators' clients? Moreover, once a target population has been registered empirically, do its members remain 'objects of inquiry' or are they promoted to full-fledged inquirers capable of challenging the original investigators' findings and methods? Probably the most sophisticated treatment of these questions in the context of positivistically inspired US social policy research is to be found in Campbell (1988).

These delicate questions arise because ultimately positivism turns Plato on his side by converting a static hierarchy into a temporal order. Where Plato imagined that authority flowed downward from the philosopher-king in a caste-based social structure, positivists have envisaged that all of humanity may pass (at a variable rate) through a sequence of stages that retrace the socioepistemic journey from captivity to autonomy. In the positivist utopia, it is possible for everyone to be an expert over their own domain. Moreover, there is a recipe for the conversion of Platonism to positivism. It proceeds by isolating a domain of inquiry from the contingencies surrounding its manifestations so that its essential nature may be fathomed. Whereas Plato reserved such inquiry to philosopher-kings, positivists have more often turned to state-licensed professional bodies. And instead of Plato's intellectual intuition (*nous*), positivists attempt to gain epistemic access by comparative historical and experimental methods.

This recipe can be illustrated in the work of Otto Neurath, an organizer of the Vienna Circle. He wanted to isolate the essence of the 'war economy' so that its efficient central planning mechanism can be transferred to environments where it would have more socially salutary consequences. Here Neurath anticipated what Alvin Gouldner would call the Janus-faced character of the 'welfare-warfare state,' whereby the same organizational structure (in this case, a concentration of resources in the nation–state) can have radically different consequences, depending on the supporting political environment. Neverthelesss, as Neurath's many critics pointed out, positivism seems to have inherited Platonism's political naivete, which confuses the fact that, say, the 'war economy' can be identified analytically as a feature of many societies and the analyst's ability to transfer it to new social environments – bar ring the imposition of sufficient force to hold all other environmental factors constant. If anything deserves the name of the 'positivist fallacy' it is this too easy assimilation of the forum to the laboratory. The history of positivism can be neatly captured as a Hegelian dialectic, the three moments of which are epitomized by the work of Auguste Comte (thesis), Ernst Mach (antithesis), and the Vienna Circle (synthesis). However, these moments have historically overlapped, occasionally coming together in figures such as Neurath. The career trajectories of positivism's standard bearers help explain the direction taken by their thought.

Comte was an early graduate of the *Ecole Polytechnique* who believed that its Napoleonic mission of rendering research a vehicle for societal transformation had been betrayed, once he himself failed to achieve a permanent academic post. Mach was a politically active physicist on the losing side of so many of the leading scientific debates of his day that his famous chair in Vienna, from which the logical positivists sprang, was awarded on the strength of his critical-historical studies, not his experimental work. Finally, the intellectual leader of the Vienna Circle, Rudolf Carnap, had to abandon physics for philosophy because his doctoral dissertation topic was seen as too 'metatheoretical' for a properly empirical discipline. For Carnap and others who came of age in World War I, physics had devolved into another specialized field of study, rather than – as it had still been for Einstein – natural philosophy pursued by more exact means.

Thesis: Comtean Positivism

Auguste Comte coined the word 'positivism' to refer to the positive side of the Enlightenment's essentially destructive approach to traditional social and intellectual orders. Comte agreed with the Enlightenment wits that scientific rationality is the model of social rationality, the exemplar of which is Newtonian mechanics. However, according to Comte, the French Revolution had refuted the wits' belief that people's 'natural reason' would come to light once they were freed from their captivity to religion and other traditional forms of authority. Comte thus designed positivism to replace both the church and the sovereign with scientific experts who together would function as a secular priesthood for modern society. 'Sociology,' another of Comte's coinages, referred at once to this political vision and the scientific project that would render it a legitimate form of authority.

Positivism in this basic sense has remained the philosophy underwriting science as a specialized profession of 'scientists' with an identifiable order of merit and career structure. Ironically, none of the movement's first phase protagonists – including Comte himself, John Stuart Mill, and Herbert Spencer – ever called a university home. Nevertheless, they all earned their living from producing knowledge (some would call it 'ideology'), unlike those for whom the pursuit of knowledge was a refined way of consuming wealth. In this important respect, positivism was aligned with the ascendant bourgeoisie and hostile to such aristocratic forms of learning as the gentleman-scientist and the academic humanist. Comte arrived at this position from his mentorship under Count Henri de Saint-Simon, a spiritual godfather of today's management gurus, who at the

dawn of the industrial age anticipated that organized knowledge would be the principal factor of economic production and political control in what Daniel Bell would call, 150 years later, 'post-industrial society.'

Given its explicitly anticlerical posture, positivism was more often found in medical schools and polytechnic institutes than traditional universities. (French universities did not become fully secular institutions until the Third Republic in 1870.) The medical interest is noteworthy because, in the nineteenth century, positivism was used to legitimize everything from phrenological and psychosomatic research to the experimental approach to medicine championed by Claude Bernard. What they all shared was the recognition that physical constitution plays a significant role in defining psychic, or spiritual, life. This basic assumption was sufficient to challenge religion's ministerial monopoly.

More generally, positivism's anticlericalism has been among its most powerful export values, especially in Latin America (where Comte's motto 'Order and Progress' remains emblazoned on the Brazilian flag). Without a thoroughgoing Protestant Reformation, Latin Americans found Comte's secularized version of Catholicism much less utopian than did their European counterparts. To be sure, background cultural allegiances divided positivist loyalties, with Francophile Latin Americans (e.g., Brazil) preferring Comte and Anglophile ones (e.g., Argentina) Spencer. In either case, though, positivism was equally likely to justify authoritarian and democratic regimes. Perhaps the most lasting intellectual residue of positivism's Comtean origins has been the default association that social scientists make between reliable knowledge and statistically significant empirical correlations. Hempel (1942), the canonical positivist account of historical explanation, placed the Vienna Circle's distinctive stamp on this point. Nowadays, its import is easily lost in methodological discussions that trivialize correlations as deficient accounts of causation, proof that positivism owes too much to Francis Bacon. However, following Karl Pearson, perhaps the first self-declared positivist to hold a professorship in Britain, the appeal to correlations served at least four distinct functions.

First, correlations enabled an economy of thought by summarizing observations already made. This would decrease the likelihood of 're-inventing the wheel,' thereby expediting overall human progress. Second, correlations forced investigators to look beyond the singular striking success to more generalizable, albeit mundane, tendencies. Here the positivism helped moderate the hype surrounding new inventions and discoveries. Third, the focus on correlations implied that scientific work could be mechanized by treating individual experiences as instances of more general types. This helped dispel the idea that scientists must have a special 'genius' for finding hidden causes beneath the welter of data. Fourth and probably most significant in Pearson's own turn-of-the-century context, the appeal to correlations echoed the 'uniformitarian' approach to natural history championed by Darwin, whose theory of evolution presupposed that all biological change has occurred by principles that emain in effect today. Thus, there was no need for either a divine creator behind the scenes whose actions transcend observed correlations or a mystification of statistically extraordinary events as 'miracles.'

Antithesis: Machian Positivism

Ernst Mach symbolized the second moment of positivism's dialectic: he gave the movement a dose of its own medicine, namely, a scientific sense of science's own limitations. Mach's counsel emerged in the midst of the ironic, perhaps perversely self-defeating, character of *fin de siecle* Viennese culture, whereby Karl Kraus's quip that psychoanalysis is the disease for which it is cure was eventually incorporated into positivistic lore as Ludwig Wittgenstein's dark saying that philosophy is the ladder that must be climbed in order to be discarded (Janik and Toulmin, 1973).

In the long term, this sense of scientific self-restraint has made its strongest impression in the dual doctrines of 'value neutrality' and 'academic freedom,' which are most closely associated in the social sciences with Max Weber. Although these doctrines normally are treated as separate, it is difficult to motivate either without examining their historical interconnection. The missing link is the idea that, absent further empirical demonstration, the value of theoretical discourse – the most obvious epistemic marker distinguishing experts from the lay public – is purely heuristic. Theory enables those who already know something to know much more; however, it obscures the vision of those who have yet to know anything.

Thus, the various Mach-inspired positivist projects of 'reducing' theoretical discourse to its empirical bases have been motivated by a keen sense of the contingency of when and where new scientific insights arise. The distinction that Hans Reichenbach and Karl Popper drew between the contexts of discovery and justification canonized this point for contemporary philosophy of science. The unique means by which a discovery is made is neither necessary nor sufficient for demonstrating its validity. Elementary logic textbooks demonize the failure to abide by this point as the 'genetic fallacy.' For Mach, the contingent nature of discovery places a special burden on scientists to render their insights as widely as possible, without denying themselves the right to follow it up in their own way. The Vienna Circle positivists may be seen as having compromised this legacy by limiting the context of justification to the received canons of inductive and deductive reasoning. But perhaps they had good reason.

Mach may have been too keen to let the lay public draw whatever conclusions they wished from their studies of science. The second moment of positivism enabled the conversion of scientific knowledge into a pure instrument detached from any prior theoretical or normative commitment. In practice, this 'neutral' stance made science available to the highest bidder, who in turn could hold a monopoly over its use (or nonuse). Consider the fate of the law of diminishing marginal utility (LDMU), which states that if there is enough of a good to satisfy a basic level of need, then each additional increment of the good satisfies the need less than the previous increment. LDMU first appeared in John Stuart Mill's normative political economy, the source of modern welfare economics. The German translation of Mill's *System of Logic* in 1849 had introduced the first phase of positivism to Mach and such contemporaries as Wilhelm Wundt and Wilhelm Dilthey, initiating the long-standing debates over the reducibility of the methods of the *Geisteswissenschaften* (Dilthey's rendering of Mill's 'moral sciences') to those of the *Naturwissenschaften*.

While Mill's later work, *On Liberty*, would inspire Mach's own views linking academic freedom to the right of dissent, Mach refused to follow Mill in drawing normative conclusions from putatively scientific facts, even though Mill's aim of removing the accumulated advantage of the rich was close to Mach's own heart.

Mill treated LDMU as a scientific basis for redistributionist social policies. He inferred that each additional increment of income earned by the rich would improve their lives less than the same increment transferred to the poor. Mill presumed a common standard of interpersonal utility and the idea that different interpersonal endowments could be explained as reversible historical accidents. Moreover, he modeled LDMU on a certain interpretation of Newton's laws, which holds them to be true in an ideal physical medium but not in actual physical reality. Thus, Mill made the ideality of the scientific laboratory stand for the normative basis of social reform. What is now called the 'marginalist revolution' in economics reinterpreted the Newtonian precedent for LDMU in the value-neutral terms that captured the social situation of Mach and other second generation positivists who called a university home.

In the 1870s, Mill's academic nemesis, William Stanley Jevons, had begun interpreting LDMU as the emergent product of interactions between agents whose respective utilities are in principle incalculable, that is, an empirically stable resolution of unknowable constitutive forces. Today we would say that LDMU is a macrolevel market effect, in which the parameters of the relevant market are left unspecified. Thus, cases that fail to conform to LDMU do not force a difficult normative judgement about whether the law or the case is at fault; rather, one casts around for an appropriately defined market to which LDMU might apply, since one may not have considered all the effects over a large enough scale, over a long enough period.

Second generation positivists came to regard LDMU as holding no clear implications for social policy. This opened the door to the curious twentieth century 'noninterventionist' policies that Milton Friedman and others have used to oppose scientific justifications of the welfare state. Here positivism's antitheoretical and antinormative stance is explicitly identified with the inductively self-organizing order of the so-called invisible hand. The shift from Jevons to Friedman is indicative of what logicians call the 'modal fallacy': The denial that X implies Y is interpreted to mean that X implies not Y, where X=LDMU; Y=State-managed redistribution of income. Thus, an economic principle that was seen originally as not necessarily licensing a particular policy intervention came to be seen as an outcome that obviates the need for any policy intervention whatsoever.

Nevertheless, the transition between the first two moments of positivism was neither smooth nor clearly separated from the third. Free market liberals continued to invoke Comte's original sense of positivism to stigmatize large-scale, usually Marx-inspired, social planning of the economy (e.g., Hayek, 1952). A target of these studies was Vienna Circle organizer, Otto Neurath, who supposed that a specialist understanding of the persistent underlying structures of political economy provides a better handle on social policy than the spontaneously aggregated experiences of individual producers and consumers. While Neurath's Marxist orientation to social planning was close to Comte's privileging of expert over lay judgement, he also accepted the Machian view that useful knowledge should be spread as widely as possible. In that sense, Neurath's interest in designing an ideographic language ('Isotype') to enable the populace to understand capitalism's inequities was born of the same impulse as his debates with Rudolf Carnap over the construction of the 'protocol statements' that constitute the fundamental language of science. Here the second moment of positivism naturally shades into the third.

Synthesis: The Vienna Circle

The Vienna Circle was started by Moritz Schlick, another physics-trained philosopher who succeeded Mach to the chair of the history of inductive sciences at the University of Vienna. Much has been made of the Vienna Circle's preoccupations with the conceptual and empirical foundations of science, the demarcation of science from nonscience, and the unification of the special sciences under a single metaphysical and/or methodological rubric. Less has been said to explain the Circle's partial return to positivism's communitarian and authoritarian origins, especially after Mach had made positivism virtually synonymous with the liberalization of epistemic authority. Nevertheless, there were few true liberals in the Vienna Circle: Schlick and Wittgenstein were conservatives, Carnap and Neurath socialists. Popper, the Circle associate closest to Mach's own politics, was not easily accepted into the fold.

This antiliberal turn can be explained by changes in science's social relations in the German-speaking world over the first quarter of the twentieth century. Seen against this background alone, the Vienna Circle appears utopian and even prone to nostalgia; but with Nazism's ascendancy in the 1930s, the 'logical positivist' movement quickly acquired a defiant and progressive cast. At first, the Circle recoiled from Machian positivism because of the ease with which Mach's neutral instrumentalism allowed scientists, especially chemists, to harness their knowledge for aggressive military–industrial ends. Consequently, Germany's humiliating defeat in World War I paved the way for the antiscientific backlash of Weimar culture that formed the backdrop to the Circle's meetings. In recognizably Platonic fashion, the Circle forged a philosophy that protected science from this backlash, while divesting it of any potentially corrupting links to technology. The key was the idea that a genuine science must satisfy certain logical and empirical criteria relating to the public testability of knowledge claims. The model for this requirement was ongoing debates over the foundations of mathematics, which Carnap and Reichenbach had already transferred to debates over the presuppositions of relativity and quantum theory.

However, one decidedly anti-Platonic insight that the Vienna Circle retained from Mach, which increased in importance over the years, was that esoteric forms of knowledge must be 'reducible' to their core 'cognitive' components so as to facilitate both their evaluation and utilization. Specifically, the Vienna Circle aimed to demystify 'metaphysical' jargon that encoded prejudice without extending insight. (Carnap famously cited Heidegger in this respect.) At the peak of its popularity in the 1940s, logical positivism was linked with such American best sellers of the 'general semantics movement'

as Hayakawa (1978). Here the foe had shifted from Heidegger to Hitler, with the positivists arguing against the irrationalism of mass propaganda. Perhaps the most famous single work of the positivist movement, Ayer (1936), written by the British observer at the Vienna Circle, can be seen as a transitional work between these two phases.

Given this history, logical positivism appears in a rather ironic light in the highly publicized *Positivismusstreit* that transpired in 1961–8 between Karl Popper and Frankfurt School doyen, Theodor Adorno. It turns out that both Popper and Adorno demonized 'positivism' in social science for the exact same ills as the logical positivists had demonized Heidegger and Hitler a quarter-century earlier, namely, a 'jargon of authenticity' and its contribution to an 'authoritarian personality' (two relevant Adornian phrases). Moreover, the two antagonists presupposed the logical positivists' ideal of unified inquiry and the inadequacy of defining society as simply the totality of 'social facts.' Where Popper and Adorno clearly differed from the positivists was over the latter's promotion of a sharp fact-value distinction, whereby the presumed unity of factual knowledge offsets the irreducible plurality of value orientations. Here positivism courted a 'relativism' that both antagonists strongly opposed. Nevertheless, the ascendancy of relativism, in the guise of 'postmodernism,' would render Popper and Adorno's wranglings over 'critical reason' beside the point by the 1980s.

In detecting positivism's latent relativism, Popper and Adorno not only anticipated the future; they also recalled the 'value neutrality' that had originally turned Machian positivism into a vehicle of power politics. In the social sciences, Max Weber's distinction between charisma and bureaucracy as modes of legitimation enabled both politicians and scientists to turn a blind eye to each other's activities, as the two groups were supposedly driven by radically different normative orientations: the politician acts, while the scientist provides reasons. Similar criticisms have been made of other movements in the social sciences affiliated with positivism, most notably Hans Kelsen's legal positivism and B. F. Skinner's radical behaviorism. Yet, even Neurath was happy to call his project 'neutral Marxism.'

These cases are united by a refusal to blur the boundary between science and politics, which in practice has meant a rejection of social democratic, welfare-state policies in favor of more extreme political stances: either complete withdrawal or outright authoritarianism. Once again, positivism would seem to have fallen victim to the modal fallacy: because politics and science can contaminate each other, therefore they inevitably will, and hence each must be left to its own devices.

Final Assessment: Does Positivism Have a Future?

After the leading members of the Vienna Circle migrated to the US in the 1930s, logical positivism seeded that country's analytic philosophy establishment for the second half of the twentieth century. However, this is the only context in which positivism possibly dominated an established discipline. For the most part, positivism has been embraced by disciplines that have yet to achieve academic respectability, even in the natural sciences, where Mach found his strongest support among chemists, biomedical scientists, and psychologists – not physicists. (It is often overlooked that positivism's reliance on Newtonian mechanics as the model for all science generally was not appreciated by a physics community jealous to guard its guild privileges.) Unsurprisingly, positivism's most ardent supporters have been social scientists, not for the Comtean reason that sociology is the pinnacle of all science but for the more mundane reason that positivism seemed to offer a strategy for rendering one's activities 'scientific.'

These matters came to a head with the publication of Kuhn (1970), which Carnap enthusiastically endorsed as the final instalment of the logical positivists' *International Encyclopedia of Unified Science*. It provided an account of scientific change based largely on the history of physics that was quickly embraced by social scientists, as Kuhn stressed science's self-organization over its larger societal impact. However, unlike previous positivist accounts, Kuhn's explicitly fixated on particular scientific disciplines (or 'paradigms') without presuming that science as a whole is heading toward a unified understanding of reality. By implication, then, all scientific standards are discipline-relative. Kuhn's approach suited what is now called the 'postmodern condition,' which the *Positivismusstreit* had desperately tried to stave off.

In retrospect, the popularity of Kuhn (1970) is better understood as signifying positivism's decadent phase than, as it was originally seen, a fundamental challenge to positivism. The decadent state of contemporary positivism can be gleaned from the ongoing debates over the scientific status of 'sociobiology.' Each side of the debate captures part of the positivist legacy: proponents like E.O. Wilson hark back to positivism's Comtean vision of unified knowledge in aid of societal transformation, while opponents like Richard Lewontin draw on positivism's more recent restriction of the bounds of science to discipline-specific criteria.

If positivism has a future, it lies in rekindling a sense of 'Science' that transcends the boundaries of particular scientific disciplines. This is how Comte originally thought about the discipline he called 'sociology.' He claimed that it was the last to develop, not simply because of the complexity of its human subject matter, but more importantly, sociology had to reconstitute the (natural) sciences that historically preceded it. Too often the history of positivism's quest for unified science has been interpreted as exclusively a matter of applying the methods of physics to less developed sciences. The reciprocal movement is really more important, namely, the application of sociological findings to the future direction of science as a whole. Such interdisciplinary projects as 'social epistemology' and the 'science of science' have tried to fulfill this side of the Comtean promise, which may be redeemed once the present intellectual climate changes.

Abstract

Positivism and sociology have a common origin, and positivism remains a significant approach in sociology and the other social sciences. In positivist sociology, the scientific study of the social world is identified with empirical research, statistical methods, and often the pursuit of general laws of social life which can be tested against experience.

The Rise of Positivism

Auguste Comte (1798–1857) argued in his *Course of Positive Philosophy* (1830–1842) that the various sciences developed through three stages – theological, metaphysical, and, eventually, positive. A positive science does not rely on spirits or abstract forces but on precise relationships of the kind expressed in Newton's law of gravity. The sciences move gradually into the positive stage, with sociology representing the culmination of this process, in the work of Comte himself. Comte, a strong influence on John Stuart Mill (1806–73) popularized the name 'sociology' to refer to what had earlier been called social physics, and a positivist approach was taken forward in sociology by Herbert Spencer (1820–1903) and later Emile Durkheim (1858–1917). Spencer made much of the parallels, as he saw them, between biological and social evolution and between societies and (other) organisms and the functional relations between their component parts. Durkheim's evolutionism was more muted, though his study of religion looked to Australian totemism for the *Elementary Forms of Religious Life* (1912) and his earlier *Rules of Sociological Method* (1895) argued for the study of 'social facts' as 'things.' Insisting on the distinctiveness of sociology and in particular its difference from psychology, Durkheim argued, notably in his classic study of *Suicide* (1897), that one should look for the social causes of regular differences in suicide rates in religious attachments or marital status, rather than invoking psychological explanations or speculating about the motives of suicidal individuals. Durkheim's distinction between 'normal' and 'pathological' states of society echoes Comte's principle that science can lead to prediction and thereby to the control of natural or social processes.

Positivism also had a presence in the study of history, for example in the work of Henry Thomas Buckle (1821–62) and others across Europe, and it was in Germany that this provoked the strongest antipositivist reaction, with the philosopher of history J.G. Droysen (1808–84) and his contemporary Wilhelm Dilthey (1833–1911), insisting on the distinctiveness of what came to be called the 'human sciences' or Geisteswissenschaften. In these sciences, as Dilthey put it, the mental activity of humans and of some other animals, and its products, can be *understood*. Dilthey developed what we would now call a research program for history and the other human sciences based on the distinctiveness of human psychic expressions and the understanding of those expressions. In a move which was to become a definitional feature of later interpretive social science, Dilthey emphasized the continuity between everyday understanding and more formal processes of interpretation.

In sociology, Georg Simmel (1858–1918) and Max Weber (1864–1920) also argued strongly for the importance of understanding (Verstehen) in history and the other social sciences, and Weber presented in his posthumously published *Economy and Society* (1920) the principle that sociology, as he conceived it, should attempt the interpretive understanding of social processes in order to explain them. His earlier classic study of *The Protestant Ethic and the 'Spirit' of Capitalism* (1904–1905) had applied this two-track approach by first showing (at least to his own satisfaction) that ascetic protestants such as Calvinists were *in fact* more economically innovative than Catholics in early modern Europe and then offering an explanation which '*made sense*' of their conduct.

By 1920, then, Weber had developed a strong alternative to positivistic sociology and offered a way of combining understanding and causal explanation which continues to attract many sociologists. In the years following his death, however, sociology became more polarized between more radical versions of both positivist and interpretivist approaches.

The Vienna Circle and the Transformation of Positivism

Positivist philosophy of science had taken a strongly empiricist direction in the work of Ernst Mach (1838–1916) who inspired the Vienna Circle, which met regularly in 1910–12 and again from 1926 into the 1930s. These physicists, mathematicians, and philosophers founded the Ernst Mach Society in 1928 and published, in 1929, a manifesto under the editorship of the sociologist Otto Neurath (1882–1945) (Neurath et al., 1929).

Comte's positivistic conception of science had stressed theory and opposed empiricism, arguing that "the next great hindrance to the use of observation is the empiricism which is introduced by those who, in the name of impartiality, would interdict the use of any theory whatsoever" and that "No real observation of any kind of phenomena is possible, except in as far as it is first directed, and finally, interpreted, by some theory." Viennese positivism or logical empiricism drew more on the formalization of logic and mathematics in the early years of the twentieth century and its extension to the philosophical analysis of language by Ludwig Wittgenstein (1889–1951),

whose *Tractatus Logico-Philosophicus* (1922) was a strong influence on members of the Circle. As they saw it, language maps onto the world through precise observation statements, to which the language of science has to be ultimately reducible. Whereas Comte had stressed the distinct domains of the various sciences, on this model the social sciences were reducible to psychology and ultimately to physics, which was no longer just the lead science in the march toward a positive state, as it had been for Comte, but the fundamental basis of 'unified science.'

This approach was disseminated in the 1930s as the members of the Vienna Circle fled from Nazism, with several figures settling in the United States, where a similar approach to science had developed independently (Platt, 1996). (The American physicist Percy Williams Bridgman's operationalism, had, for example, been a major influence on the Vienna Circle itself.) Two philosophers who popularized logical empiricism were Alfred Ayer (1910–89) in the United Kingdom and Karl Popper (1902–94), who emigrated from Austria to New Zealand and then also settled in London. Popper introduced the most important modifications to the Vienna Circle model and also addressed issues of social and political philosophy. One of the central principles of logical empiricism had been the 'verification principle,' the Bridgmanian idea that the meaning of an empirical statement depends on, or in some versions is identical with, its means of verification. (One consequence, enthusiastically promulgated by Ayer (1936), was that value judgments were meaningless, being neither empirical nor logical or mathematical.) Popper (1934) demonstrated the impossibility of conclusive verification in science and stood the problem on its head, arguing that testability was better understood in terms of falsification. The statement that all swans are white can never be conclusively *verified*, unless we are sure that we have observed all swans that ever existed and that they are now extinct, whereas the statement can be *falsified* by the observation of just one black swan. Scientific theories expose themselves to testing, as Einstein had done by making a prediction about the position of Mercury which was proved accurate in 1910. In Popper's analysis, this did not prove the theory but merely gave it greater 'verisimilitude' since it had passed a crucial test. Like a car which has passed an annual safety inspection, it could be conditionally relied on until the next time. Pseudotheories by contrast, such as Marxism and psychoanalysis, could amass lots of supporting evidence but did not expose themselves to falsification. Social science, Popper argued, could make conditional predictions, but should avoid the temptation of 'prophecy.'

Positivism and Sociology

This modified version of Viennese positivism has been massively influential in the philosophy of science, including social science. Popper had undercut the search for certainty which had been the Achilles heel of logical empiricism and offered an alternative model of scientificity. In the social sciences, new quantitative techniques were developed for theory testing, and punched cards gave way to computers. In the 'covering-law' model of causal explanation, empirical findings were attached to general laws in the manner alleged to operate in the natural sciences. (In the classic example, the general law that water freezes at 0° explains the state of my car radiator after a cold night.) This covering-law approach to explanation coexisted with the rise of functionalism; Talcott Parsons suggested, quite implausibly, that his system theory might one day be open to empirical testing. Max Weber's plea for the avoidance of value judgments *in social science* (which in Weber's practice coincided with an almost existentialist position on our choice of ultimate values and a variety of intensely political engagements) became the dominant position justifying an *apolitical* stance for social science – which in practice tended to mean an endorsement of the ideological status quo.

However, the history of positivism, like that of Stalinist economic planning, is largely the history of attempts to modify or reform it, and it unraveled from a number of directions. In philosophy, thinkers influenced by North American pragmatism such as W.V.O. Quine (1908–2000) emphasized the importance of theoretical frameworks, questioning the idea of piecemeal testing or instance confirmation. More seriously for Popper, the historian of science Thomas Kuhn (1962) showed that scientists tend to work most of the time within unquestioned frameworks or 'paradigms,' switching from one to another only in periods of scientific revolution, in a process close to religious conversion. Paul Feyerabend (1924–94) drew the extreme conclusion that a good empiricist should be an epistemological anarchist and accept that 'anything goes': all theories should be taken seriously. Wittgenstein (1953) had dropped his earlier theory of language in favor of a much more holistic and sociological approach to 'language games' located in 'forms of life.' This linked up with antipositivist interpretive approaches in sociology and social anthropology, as demonstrated by the British philosopher Peter Winch (1958). Meanwhile the Canadian philosopher Charles Taylor (1964), influenced both by analytic philosophy and by continental European hermeneutics, argued that the behavior of humans and other higher animals should be understood in terms of intentions and purposes rather than just causal impulses.

In a further twist, Karl-Otto Apel (1967) demonstrated in more detail the affinities between analytic philosophy of language and the Geisteswissenschaften tradition, and Jürgen Habermas, who had joined in the critique of positivism in West German sociology in the early 1960s (Adorno et al., 1976), showed how phenomenology, analytic philosophy and Hans-Georg Gadamer's version of philosophical hermeneutics could combine against social scientific positivism and yield a 'critical social science' (Habermas, 1968a,b). This type of science combined causal explanation and understanding in an approach, exemplified by psychoanalysis and the marxist critique of ideology, which identified and removed causal obstacles to understanding. Positivism, for Habermas (1968b: p. vii) and his associate Albrecht Wellmer (1967), meant an absence of reflection and the reduction of epistemology to methodology, whether in natural or social science. In the latter case, however, the imitation of a natural scientific model was particularly dangerous because it reinforced tendencies to technocracy which undermined the possibilities of political deliberation. Habermas later reformulated his model of emancipatory science, but it remains in a modified form in his idea of reconstructive sciences, which explicate capacities which we exercise in daily life. His initial example was linguistics, which identifies the rules which we

unconsciously follow as native speakers of a language, but his own theory of communicative action (Habermas, 1981) also embodies this approach.

Whereas critical theory tends toward a dualism of natural and social science, but in an increasingly muted form, the assumption that opposition to positivism also entailed dualism or antinaturalism was, however, also put in question in the late 1960s and early 1970s by the realist metatheory of science developed by Rom Harré and Roy Bhaskar. Both Harré and Bhaskar, like Habermas, were substantially motivated by the desire to undermine positivistic theories and approaches in the social sciences. They were interested in giving a more adequate account of science as a whole, in world composed of relatively enduring structures and mechanisms. Some of these could be isolated in scientific experimentation, given the contingent existence of *Homo sapiens* and *Homo scientificus*. An important aspect of the realist program developed by Harré, Bhaskar, and others was a conception of explanation as involving not an essentially semantic reduction of causal statements to general laws (which in sociology tended to be either vacuous or riddled with exceptions) but a reference to the causal powers of entities, structures, and mechanisms. The real explanation of the state of my radiator is not the mere generalization that water freezes at 0° but the causal properties of water molecules: their capacity to freeze or evaporate. Causal tendencies may be outweighed by countervailing tendencies, and two causal tendencies may neutralize one another, as do the centrifugal force of the Earth's rotation and its gravitational attraction, with the convenient consequence that human beings and other animals are safely anchored close to the Earth's surface but can jump over small obstacles.

This and other features of realism meant that the whole issue of naturalism could be rethought. Human beings could be seen as having causal powers and liabilities, just like other entities; it no longer mattered if their relations rarely sustained any universal generalizations of an interesting kind, but only sets of tendencies regular enough to be worth exploring. It also seemed natural to include among the causes of human action the agents' reasons for acting – reasons which must be understood as far as possible. Reasons, such as a smoker's reasons for giving up the habit, might form part of a causal explanation of the cure. The fact that many of the entities accorded causal force in social scientific explanations were necessarily unobservable was not, as it was for empiricism, a problem of principle. And the understanding of meaning could, as Bhaskar (1979: pp. 58–59) put it, be seen as in some ways equivalent to measurement in the natural sciences. Realists diverge on the issue of naturalism, with Bhaskar arguing for it and Harré defending a more interactionist and social constructionist position, focusing on interpersonal action and questioning the existence of social structures.

Realism found a more comfortable home in sociology and the emergent discipline of international relations than in academic philosophy, and in Britain and Scandinavia more than in other parts of Europe or in North America. Together, however, all these antipositivist currents meant that it was even harder than before to find explicit defenders of positivism. Jonathan Turner (1981, 1985, 1992, 2013) in the United States is a significant example, and Peter Blau also identified explicitly with positivism. For the most part, however, positivism tended to be equated, by both supporters and critics, with empirical research and in particular with quantitative methodologies. Turner is an exception, since his positivistic defense of scientific theory in sociology was also highly critical of the vogue for quantification in the United States. As he noted in an earlier version of this article, positivist books on 'theory building' and 'theory construction' in the late 1960s, beginning with Hans Zetterberg's (1965) *On Theory and Verification in Sociology* and continuing through the 1960s and 1970s (e.g., Blalock, 1969; Dubin, 1969; Gibbs, 1972; Hage, 1972; Reynolds, 1971), did not retain their initial appeal at a time when functionalism was also going into decline.

As the theoretical wave of the later twentieth century passed over sociology and began to dissipate, with more interdisciplinary conceptions of 'social theory' tending to break away from mainstream sociology, the theoretical debates between positivism and hermeneutic and other antipositivist approaches tended to be trivialized into a choice between quantitative and qualitative methods or between 'empiricism,' identified with any empirical research, and 'theory,' meaning any sociological work not involving empirical research. Some prominent figures labeled as theorists did empirical research, for example, Pierre Bourdieu in France; others, like Zygmunt Bauman or Anthony Giddens in the United Kingdom, did not, but this was not generally felt to be a significant difference.

The Prospects for Positivism

Positivism in the very general sense of an aspiration to scientificity and to the construction and empirical testing of formal theories remains a significant presence in contemporary sociology, and to a much greater extent in economics, political science, and some parts of international relations. As Peter Halfpenny (2001: p. 382) notes,

> …large numbers of investigators continue to produce research that conforms to the positivist image of science, explaining social activities in loosely deductive-nomological terms, and these explanations are used to guide and evaluate a wide variety of social programmes.

It may be that the important dividing line is now between formal conceptions of theory and more informal ones such as the 'theory' of structuration or risk society or theoretical approaches such as actor-network theory. This dividing line (Turner, 2013; Outhwaite, 2014) runs through several theory families, such as rational choice or rational action theory, which encompasses a highly formalized, even formalistic mainstream, following Gary Becker (1976), and more flexible and sophisticated approaches such as those of Martin Hollis (1938–98), for whom "rational action is its own explanation" (Hollis, 1977: p. 135) or Jon Elster (1989, 2007). Hollis and Nell (1975) deconstructed the powerful alliance between positivism and neoclassical economics, while Hollis and Smith (1990) provided what

remains one of the best statements of what is at stake in the oppositions between 'explaining' and 'understanding' in the social sciences and between 'agency' and 'structure.' As Smith wrote in the exchange with which they end the book:

> I, too, reject the Positivist notion that there is a world waiting to be mapped. There may be regularities in human affairs but I do not accept the idea that we can construct a neutral theory, valid across time and space, that allows us to predict in the same way as occurs in the natural sciences. (Hollis and Smith, 1990: p. 203)

Evolutionary sociology, mentioned above in relation to Herbert Spencer, has recently experienced a certain revival, though in forms which are mostly dismissive of Spencer's earlier efforts (O'Malley, 2007). Marxism is another example, with formal and mathematical reformulations of central Marxist propositions (including French structuralist Marxism, analytical Marxism, also known as 'no-bullshit Marxism,' and 'rational choice Marxism'), coexisting with more humanistic variants which shade off into critical theory, in both its Frankfurt School and broader literary and cultural variants. As Peter Halfpenny (1982: p. 120) concluded,

> Positivism may be dead in that there is no longer an identifiable community of philosophers who give its simpler characterisations unqualified support, but it lives on philosophically, developed until it transmutes into conventionalism and realism.

Since then, the term 'postpositivism' has come into use. Like most 'post' formulations, it tends to be used in a wide variety of senses, ranging in this case from modifications of an essentially still positivist program to strong versions of social constructionism (Alvesson and Sköldberg, 2010). 'Positivism' has tended to become a term of abuse, while the positivistic impulse toward formalization and (presumed or hoped-for) certainty continues to pervade our increasingly rationalized and performance-oriented social sciences.

Abstract

In linguistics, possession is conceived as a relationship of appurtenance between a possessor and a possessed (*possessum*, *possessee*) for which there are specific paradigms of expression in the languages of the world. On the conceptual side, this relationship of appurtenance ranges from material possession via kinship and body-part relationships to the domain of abstract relations (someone's ideas, someone's activities, etc.). On the formal side, one distinguishes mainly between attributive possession (e.g., 'my house,' 'the man's house') and predicative possession ('the house is mine,' 'the house belongs to me,' 'I have a house'). However, it is not always easy to distinguish the conceptual domain of possession from other cognitive domains, and also on the formal side there is a continuum of expression rather than some strictly defined set of constructions. Especially in the area of inalienable possession (body parts, kinship relations) one often finds peculiar constructions where the possessor of body parts is 'raised' to become an argument of the verb as in 'he hit me on the head' versus 'he hit on my head.' Generally speaking, the proper understanding of linguistic possession includes matters of the relative discourse prominence of possessor and possessum in the event described, depending on criteria like animacy, egocentricity, etc.

In linguistics, possession is conceived as a relationship of appurtenance between a possessor (P'or) and a possessed (P'ed, possessum, possessee) for which there are specific paradigms of expression in languages of the world. On the conceptual side, this relationship of appurtenance ranges from material possession via kinship and body-part relationships to the domain of abstract relations (someone's ideas, someone's activities, etc.). On the formal side, one distinguishes mainly between attributive possession (e.g., 'my house,' 'the man's house') and predicative possession ('the house is mine,' 'the house belongs to me,' 'I have a house').

However, it is not always easy to distinguish the conceptual domain of possession from other cognitive domains, and also on the formal side there is a continuum of expression rather than some strictly defined set of constructions. For instance, in many languages (e.g., in English or Icelandic) constructions like 'I have ploughed an acre' (expressing an event in time) historically go back to possessive expressions whose literal meaning was 'I have an acre as something ploughed,' and there are also numerous ways of crossing the boundary between attributive and predicative sentential constructions. For instance, many languages alternate between attributive constructions like German *der Sohn des Mannes* (ART:NOM son:NOM ART:GEN man:GEN, 'the man's son'; where ART = article, GEN = genitive, NOM = nominative) and *dem Mann sein Sohn* (ART:DAT man:DAT his:NOM son:NOM, lit. '(to) the man his son'), where the dative constituent (DAT) functioned originally as an indirect object in predications like *sie entführten dem Mann seinen Sohn* (they:NOM kidnapped ART:DAT man:DAT his:ACC son:ACC, lit. 'they kidnapped (to) the man his son'; where ACC = accusative). These latter constructions (which are typically associated with some psychological involvement on the part of the P'or) are known as *dativus sympaticus*-constructions or are referred to in the context of possessor raising or external possession.

Since psychological involvement also correlates with the relative 'closeness' and 'inalienability' of the possessive relation, it is customary to distinguish between constructions for inalienable and alienable possession. Alienable possession normally refers to material belongings as opposed to kinship and body-part relationships, and there are many languages that have standardized formal ways of distinguishing these domains. One has to bear in mind, however, that the main purpose of these constructions is not the expression of possession as such (see below). Rather, these constructions typically reflect considerations of discourse pragmatics with respect to two nominal referents. In other words, while the concept of possession extends beyond linguistics, the formal category of possession carries properties that are specific to language and linguistics, respectively. This suggests that to a certain extent linguistic possession must be differentiated from nonlinguistic concepts of possession.

Approaches to Possession

The Literature on Possession

The linguistic literature on possession concentrates on rather different aspects. Seiler's monograph (Seiler, 1983) is still the most comprehensive attempt at dealing with the cross-linguistic spectrum of constructions, which according to Seiler can be placed on a formal and semantic continuum in the domain of possession (see Section Details on Typological Research on Possession below). Heine (1997) and, more recently, Stassen (2009) focus mainly on predicative possession and on typical ways in which such constructions develop in the process of grammaticalization. Attributive possession is usually extensively described in traditional grammars under the headings of possessive pronouns and genitival constructions. McGregor and Chappell (1996) focus on the typology of inalienable possession, and Payne and Barshi (1999) focus on the typology of external possession. Other publications include discussions on the grammatical status of specific items from the domain of possession. For instance, it is sometimes

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52040-6

unclear whether possessive pronouns behave like genitival arguments or like adjectives. The discussions in this area are rather technical and must be seen in the context of DP-analysis (for reference see Abney, 1987; Löbel, 1995). As far as language typology is concerned, in the last decade, substantial work has been added on the various ways in which possession is expressed in many different languages of the world, for instance by Motoki (2010), Grkovic-Major (2010), Gunkel and Zifonun (2011), Koptjevskaja-Tamm (2002, 2003), McAnallen (2011), and Stassen (2009). Also the *World Atlas of Language Structures* by Haspelmath et al. (2005) presents an abundance of typological and geolinguistic facts. In what follows, this article will focus on some important issues from the typology of possessive constructions.

Details on Typological Research on Possession

The most difficult problem for the typological description of possession is the great variety of expression and the fact that there is no simple correspondence between a conceptual relationship of possession and traditional linguistic categories like possessive pronouns or possessive verbs (in fact, possessive verbs are cross-linguistically rather rare). For instance, a Latin construction like *mihi est liber* (me:DAT is book:NOM, lit. 'to me is (a) book') contains no 'classical' possessive category, but conceptually it figures as a possessive construction. Conversely, a construction like 'my train' in 'I've got to catch my train' does not really refer to the train which I own, though it does involve a 'classical' possessive pronoun. Finally, there are instances of so-called 'possessor deletion' as in the German *er hob die Hand* (lit. 'he raised the hand') versus the English 'he raised his hand,' which unlike the German example contains an explicit possessive pronoun.

As a solution to these problems, Seiler (1983) proposes that the expression of possession constitutes a cognitive operational program ranging from minimal explicitness of the relationship (indicativity) to maximal explicitness (predicativity). Indicativity literally means to 'point' at what one may take for granted, while predicativity establishes a relationship by overt means. The 'indicative' and less explicit techniques are mainly characteristic of the attributive pole (with the same constructions ranging from the clearly possessive 'my house' to fairly unspecific relations like 'my train'), while explicitly possessive verbs belong to the most predicative type of construction (with constructions like 'I own a house').

In this context, it is no coincidence that inalienable, inherent possessive relationships usually need less formal 'effort' to be encoded than alienable relationships – as the relationship is usually self-understood, it literally goes without saying. For example, in the Amerindian language Cahuilla the expression 'his eye' would just involve the direct juxtaposition of an uninflected personal pronoun and the lexical stem for 'eye,' while the expression 'his dog' needs the addition of a 'possessive classifier' meaning 'pet': compare *he-puc* (3.SG-eye, 'his eye'; where SG = singular) versus *he-ʔas ʔawal* (3.SG-pet dog, lit. 'his pet dog'). Here, the (inalienably conceived) body-part term 'eye' is inherently relational, such that the possessive relation between 'he' and 'eye' is more or less 'self-understood' and need not be made explicit; for 'dog' the situation is different, so that the relationship between 'he' and 'dog' must be established by some relational item like 'pet.' By way of contrast, one would need far more effort in Cahuilla to use a word like 'eye' in a 'derelationalized' sense. Thus, while 'the dog' is simply *ʔawal*, 'the eye' (in some abstract sense) would be *puc-il* (eye-DER; where DER = derationalizer).

Seiler lists a number of techniques commonly employed for the expression of possessive relationships, which can all be placed on a continuum between maximal implicitness and maximal explicitness of the relationship. These techniques include plain juxtaposition of P'or and P'ed ('N–N-constructions,' see above), connectives (CONN), possessive classifiers, (possessive) cases, existential copula constructions, and possessive verbs. The Persian *iza:fa*-construction would be an example for connectives (cf *ha:ne-je pedar* (house-CONN father, 'the father's house')), and for possessive classifiers see Cahuilla. Latin *domus patris* (house:NOM father:GEN) is an instance of a case construction. A case construction is a more 'explicit' technique than the connective technique in the sense that so-called 'cases' may allow far more oppositions than all-purpose connectives, etc.; for instance, apart from using a possessive genitive, many languages also employ locatives in attributive possession (cf Modern Icelandic *höfuðið á mér* (lit. 'the head on me,' 'my head'), as opposed to *augun í mér* (lit. 'the eyes in me,' 'my eyes'), which is a fairly explicit way of specifying how the body-part relates to the P'or). Case constructions also include expressions like the German *der Mann mit dem Hut* ('the man with the hat'). Here, however, the relationship of possession is expressed from a different perspective than *der Hut von dem Mann* (lit. 'the hat from the man,' 'the man's hat'); in the former construction, the nucleus is the possessor, while in the latter the nucleus is the possessed. (For the change of perspective also see Section The Linguistic Side of Possession below.)

With the help of copulas, the case constructions can often be turned into literally predicative expressions of possession (cf the German *der Hut ist von dem Mann* (lit. 'the hat is from the man,' 'the hat belongs to the man') and Icelandic *ég er með bíl* (lit. 'I am with (a) car,' 'I have a car with me')). Finally, languages may also employ actual verbs of possession as in 'I have or own a book' and 'the book belongs to me,' etc. This technique allows the greatest number of oppositions (the number of lexical verbs is virtually limitless), and since this technique is the most predicative one in the sense of Seiler, it is hardly 'natural' in the context of inalienable and 'self-understood' possession. For example, clauses like 'I have a father' or 'I have a head' are considered deviant, unless modifications are added (cf 'I have a nice father,' 'I have a swollen head'). Nevertheless, though in principle inalienable possession tends toward the 'indicative' pole, and alienable possession tends toward the 'predicative' pole, there are always possibilities of making the implicit explicit and the explicit rather implicit. For instance, Indo-European possessive pronouns probably go back to locative constructions of much the same type as the ones which are now commonly used for attributive body-part possession in Icelandic (see above), and the Icelandic attributive constructions in question like *höfuðið á mér* (lit. 'the head on me') originate in turn from predicative *dativus sympaticus*-constructions like 'he hit (on) me on the head.' Therefore, there appears to be some shift from the more explicit and predicative to the less explicit in the process of grammaticalization. At the same time, as a reaction to

a decrease of explicitness, new explicit constructions may be coined. In this context, Seiler claims that indicativity and predicativity represent complementary principles that are in competition with each other in the operation of giving expression to conceptual possession.

Heine (1997), too, is interested in grammaticalization channels, but he concentrates on the lexical sources of (mostly nonattributive) possession and on the ultimate destiny of possessive items in other domains of grammar. As for nonattributive possession ('predicative possession' in a more restricted sense than in Seiler's framework), Heine (1997: p. 47) presents the following typology based on various conceptual 'schemata': 'X takes Y' ('action schema'), 'Y is located at X' ('location'), 'X is with Y' ('companion'), 'X's Y exists' ('genitive'), 'Y exists for/to X' ('goal'), 'Y exists from X' ('source'), 'as for X, Y exists' ('topic'), 'Y is X's (property)' ('equation'). As an example for the action schema Heine mentions Portuguese, while Turkish has a location schema. Somali has a companion schema, while the genitive schema is found again in Turkish. The goal schema is manifested in Tamil and Hungarian, the source schema manifests itself in Ik (Nilo-Saharan), Cahuilla has a topic schema, and Russian has an equation schema. In many of these languages different schemata coexist. Again, there is no clear separation between possession and very many other kinds of conceptual domains.

For the different schematic types mentioned it is possible to identify very common paths of development and transitions to other categories. Especially postural verbs (e.g., 'stand,' etc.) often develop into locative copulas, and the resulting location schema ('X is located at Y') may develop into a companion schema ('X is with Y'); both the location schema and the companion schema then tend to be reemployed as expressions of possession (for companion cases ('be with') cf Icelandic *ég er með bíl* (see above), and for location cf Finnish *Liisalla on mies* (lit. 'at Liisa is (a) husband,' 'Liisa has a husband')). The same construction types also often grammaticalize to expressions of aspect (Swahili has a 'be with'-progressive, and Icelandic has a 'be at'-progressive). Aspectual categories also commonly develop from possessively interpreted action schemata like 'to take X' (>'to have X'>'to have gone'), and aspectual categories may ultimately be interpreted as tense categories ('past tense').

Stassen (2005), too, classifies possessive categories into different types. His five categories for predicative possession are the following: locational possessive ('P'ed is at P'or'), genitive possessive ('P'ed is of P'or'), topic possessive ('as for P'or, there is P'ed'), conjunctional possessive ('P'or is with P'ed'), and the 'have'-possessive ('P'or has P'ed' and 'P'ed belongs to P'or,' respectively). As the accompanying map (which is accessible online) illustrates, the allegedly canonical 'have'-construction only accounts for about a fifth of the predicative structures actually employed in the languages of the world. There are also regional clusters: conjunctional possessives are particularly common in the southern part of Africa, while topic possessives are frequent around Indonesia (where 'have'-verbs are practically absent).

In his latest book on predicative possession, Stassen (2009) claims to have found strong structural ties between the kind of possessive structure used in this context and semantically fairly different expressions such as *John sang and Mary danced*. For instance, the predicative encoding of possession (for instance, 'be with') is paralleled by the encoding of temporal sequencing 'and then'; cf Stassen (2009: p. 90f). Granted that this is actually true, it still leaves the question why this should be the case. Why should possessive constructions be closely tied to constructions of a very different sort? Again, answers must often not be looked for in the realm of possession as such, but rather in the relevant discourse strategies (see ch. 1.3 below).

The shortcomings of traditional descriptions of possessive constructions are most noticeable in the area of inalienable possession. The *dativus sympaticus*-constructions are extremely common, and the cases used in possessive constructions for the P'or or noun phrase include not only genitives, datives, locative constructions, and the plain juxtaposition mentioned above, but occasionally even accusatives (e.g., Faroese kinship relations). As a consequence, it is necessary to give special attention to alternatives to traditional grammatical encodings of possession. The book edited by McGregor and Chappell (1996) presents a rich cross-linguistic survey of inalienable possession; common strategies associated with inalienables apart from 'he hit me on the head'-constructions are 'incorporating' strategies like 'he is bigheaded' (vs? 'he is bigcarred'). Quite typically, the P'or may not be mentioned at all on the inalienably possessed noun phrase (cf the phenomenon of 'possessor deletion' (see above)). But conversely, inherent relationality may sometimes have to be obligatorily marked (lit. 'his hands-his'). As a variant of possessor raising giving prominence to psychologically involved possessors, also different honorifics may be used in the context of body-part relations (cf Japanese, see Tsunoda, 1996).

Payne and Barshi's definition (1999: p. 3) of 'external possession' covers more than the constructions used in possessor raising: here external possession denotes any construction in which the P'or figures as a core argument of the verb and in a constituent separate from that which contains the P'ed. This definition includes applicatives (e.g., Mixean, see Zavala, 1999), 'double subject constructions,' and expressions where the P'or is the subject of a verb with an incorporated P'ed (Mohawk, see Baker, 1999). What is common to all these constructions is some difference in 'empathy,' 'discourse prominence,' and 'fore-grounding' in the relationship between P'or and P'ed as compared to the 'standard' possessive constructions. In fact, all kinds of possessive constructions can be ordered in terms of the comparative discourse prominence for P'or and P'ed. With this in mind, it is necessary to be aware of some specifically linguistic functions of possessive categories. Since surprisingly little work has been done on this aspect of linguistic possession, I will present some of the evidence for possession and discourse pragmatics in relative detail here.

The Linguistic Side of Possession

Different degrees of discourse prominence can be tested, among other things, with criteria like accessibility for relativization, etc. Languages differ considerably in the extent they 'normally' give prominence to possessors and possessed items, but there is usually variation between various options in the same language, too. Compare English, where the ordinary possessive

pronoun 'her' cannot be taken up in a relative clause, but the phrase 'of hers' can, as in 'her dog *who (=she)' versus 'this dog of hers, who (=she).' Another instance of this kind is Icelandic *bíllinn sinn, *sem* ('his car, who') as opposed to *bíllinn hans, sem* ('the car of his, who'): here, the 'eius'-possessive pronoun *hans* is a genitive form and can be taken up by a relative clause, such that the P'or gains relative discourse prominence, while the 'suus'-possessive pronoun cannot be taken up by a relative pronoun and has very little discourse prominence. The only purpose of *sinn* is to properly identify the P'ed – because *bíllinn* 'the car' would not be explicit enough. Conversely, constructions like Icelandic *Pabbi or faðurinn* ('daddy' or 'the father') may go without specification. They are inherently relational and are naturally associated with the speaker.

Yet more generally speaking, what is called 'possession' in linguistics is a special way of relating two different, but more or less salient referents in the discourse. This distinguishes possession clearly from 'identity' (same referent) and 'location' (space expressions are hardly salient or subject-worthy in the discourse). From these facts alone follow quite a lot of structures observed in the languages of the world.

First of all, it is natural in possessive expressions to find structures with two 'nominal' and thus typically referential items. This is true of genitival constructions like *the man's house*, but also of predicative constructions like Latin *mihi est liber*, lit. 'to me is (a) book,' 'I have a book,' as well as German *das Buch ist mir*, lit. 'the book is to me,' 'the book belongs to me.' It is also quite natural that the use of verbs of possession is not as frequent as the use of verbs in action scenarios – as the relationship is fairly stable in time. And speaking of discourse pragmatics, it is conceivable that mainly alienably possessed items are 'isolatable' enough to figure as subjects (cf *the book belongs to me* vs **the head belongs to me*).

If, however, for some reason, the expected 'norms' are violated, and an inalienable P'ed becomes a subject, this requires extra formal 'effort' – as, for instance, in the German phrase *mein Bauch gehört mir* 'my belly belongs to me,' which was used as a slogan of the feminist movement in the debate on abortion. Here, the possessive pronoun *mein* 'my' makes it clear that *Bauch* 'belly' is not a canonical, absolute subject. Other languages, for instance in Austronesia, employ specific possessive classifiers to indicate that the expression is not a canonical subject.

On the other hand, a possessive relationship is conceptually more controlled and closer than a locative relation, and therefore there is a tendency for original locatives to become grammaticalized as either genitives or datives in the domain of possession. And just as there is a change of perspective with respect to the use of 'P'or has P'ed'- versus 'P'ed belongs to P'or'- constructions, similar things can be said with respect to the use of prepositions. Compare, for instance, *das Buch von dem Mann* versus *der Mann mit dem Buch* (lit. 'the book from/of the man' vs 'the man with the book'). Interestingly, while we are talking about the same possessive relationship, the relation is viewed from different angles: in the ordinary, genitive-like construction with the preposition *von* 'from/of,' the P'ed is conceived as something literally 'distant from' or 'off' the main point of reference (genitives typically derive from 'off'-expressions). Conversely, the preposition *mit*, which goes back to the locative noun *Mitte*, 'middle,' marks the P'or as the actual 'middle' or 'center' of the relationship. In other words, the shift of perspective from P'or-NP to P'ed-NP is accompanied by a shift of attention from the (natural) center to the periphery or unnatural center. This interplay of center and periphery refers not to the possessive relation as such, but rather to the psychological way of observing the relation in question. In other words, psychological 'gestalt'-principles are an important structural element of language and possessive constructions, respectively (compare Broschart, 2007).

With this in mind, it comes as no surprise that attributive constructions like *das Buch von dem Mann* are far more common than *der Mann mit dem Buch* – simply because an NP like *der Mann* is usually readily identifiable as an 'isolate' figure in the discourse, while belongings are not. For this reason, *the book* usually needs an attribute, while *the man* does not.

But the story does not end here. As was shown above, there are a great many options of giving different degrees of discourse prominence to P'or and P'ed. The lowest discourse prominence for a speech act participant like 'I' or 'you' is a possessive pronoun or adjective, respectively (like Icelandic *minn* 'my' (see above)), while case forms of these pronouns (like genitives, *dativus sympaticus*, or even possessive accusatives) gain more and more discourse prominence. This is particularly true in events where the P'or is the actual target of the action (as in *he hit me on the head*).

As for common P'or-nouns, they are high in discourse prominence when they occur inside a referential (case or prepositional) phrase; prominence is lowest, however, in compounds such as German *Stuhlbein*, lit. 'chairleg,' 'the foot of a chair.' Yet even here, naturally salient, animate referents often appear with case-like items: *von Kind-es-beinen an*, lit. 'from a child's legs onward,' 'right from the age of a child.'

Thus, if there is anything that can order the incredible variety of possessive constructions cross-linguistically, it is the interplay of norm and exception with respect to subject-worthiness or relative discourse prominence, respectively. Any deviation from the norms (e.g., using a P'ed as a subject) requires additional effort (possessive pronouns or classifiers) such that the norms must not be forgotten (in Broschart (2007), I compare this to the 'cybernetic' mechanism of a thermostat in a heating system which controls the amount of energy needed, yet always relates back to normal). And it is also clear that if a relationship is self-understood, it need not be made explicit (*daddy* is sufficiently relational without the addition of *my*). Normally, there is some continuum of increasing possessor prominence from possessive pronouns via personal pronouns in the genitive to actual arguments of the verb (in the dative or accusative, etc., as in 'possessor raising' constructions). And while the P'ed is totally inaccessible for relativization in 'the blue-eyed man *which (=the eyes) …,' the P'ed can be relativized in 'the man with the blue eyes which (=the eyes) …,' etc.

As was noted earlier, in this context, possessive constructions do not simply express some extralinguistic concept, i.e., the constructions in question must also be judged with respect to their function in the discourse. This is particularly conspicuous in connection with genitival constructions. It is true that 'normally' the genitive phrase 'expresses' the possessor (cf 'the

man's car'), but sometimes the situation is reversed. Compare German *das Auto des Mannes ist alt* (lit. 'the car (P'ed:NOM) of the man (P'or:GEN) is old') versus *der Besitzer des Autos ist alt* (lit. 'the owner (P'or:NOM) of the car (P'ed:GEN) is old'). Clearly, it would be wrong to say that the genitival phrase always expresses the P'or – after all, the nucleus NP *der Besitzer* explicitly states that what follows is a possessed item. So the function of the genitive phrase cannot sufficiently be described by saying that it expresses a P'or. At best, one might say that the genitive phrase 'normally' expresses a P'or, and that in the deviant cases one has to create derived nouns like *Besitzer* to balance the effect of the deviation. However, what is generally true of the function of the genitive phrase is that it is used for the identification of the referent in the discourse.

'Normally,' it will be human P'ors who are 'better known' for identification than inanimate referents or dependent referents like body parts, etc., but in examples like German *der Besitzer des Autos mit dem Kennzeichen XY wird gebeten, sich mit der Polizei in Verbindung zu setzen* ('the owner of the car with the registration number XY is requested to contact the police'), it is the inanimate referent that happens to be better identifiable. In this case, the P'or will have to be expressed by a special relational noun (*Besitzer* 'owner'), but the genitival phrase is still basically used for identification in the discourse, even though it now encodes the P'ed.

Since discourse relevance is a direct correlate of high animacy and conceptual independence, this explains why the linguistic treatment of possessive relations will tend to be associated with distinctions like [+/-animate] and [+/-alienable]. As animacy also correlates with control just like any relationship of possession, it is not surprising that there are conceptual shifts from possession to distinctions of agency (cf 'I have beaten' (agentive) vs 'I am beaten' (nonagentive)) and vice versa. Agent (AG) and patient (PAT) are also differentiated in nominalized possessor-of-the-act constructions (cf 'Peter's (AG) beating (action) of the dog (PAT)' or Tongan *ko 'eku* (alienable) *taa'I 'o* (inalienable) *e kulí* (lit. 'it is my (active) beating of the (passive) dog,' 'I am currently beating the dog'); cf Broschart (1994)). Apart from that, agent and patient relations have also frequently been observed to coincide with differences of imperfective versus perfective aspect. And note that even the shift from an indefinite P'ed in a 'have'-construction to a definite P'ed typically leads to new aspectual constructions. Compare, for instance, German *ich habe ein Haus* 'I have/own a house' as opposed to **ich habe das Haus* (lit. 'I have the house'): the latter is considered strange and would be replaced by the more natural *das Haus gehört mir*, 'the house belongs to me.' But there are related 'have'-constructions with a definite P'or-object that tend to become reanalyzed as temporal or aspectual, as in *ich habe das Haus gekauft* ('I have bought the house' or 'I have the house as sth. bought'). Hence, from the point of view mentioned above, the typical correspondences between possession, voice, and aspect are not surprising. Like the voice distinction, possession implies some shift of perspective from an 'ordinary' discourse referent (which is animate and independent) to some referent which is usually inanimate and dependent. And the 'have'-constructions with definite objects are borderline cases of possession that tend to be reanalyzed as aspectual or temporal constructions.

It is these shifts of perspective and the many alternative forms of encoding that make possession a highly interesting domain of study for linguistics and cognitive science. But again, it must be emphasized that it is not possession as such that makes it a highly salient concept in language. For instance, cultures that originally had very little sense of personal belongings may still have hundreds of possessive pronouns – as is the case in Polynesian Tongan. And while languages differentiate very frequently between alienable and inalienable possession, I know of none that grammatically differentiates between cheap and expensive belongings.

Rather, it just so happens that many characteristics of possessive semantics correlate with important ingredients of the speech act, such as control or agency, familiarity in the discourse, etc. It is these characteristics that get grammaticalized, not some extralinguistic notion of belonging. However, knowing what belongs to whom sets the stage for many different kinds of interaction – including trade and warfare. For minimizing potentially bad effects of interaction, communication is essential – like employing a common tool which we all share – 'our' language.

Post Traumatic Amnesia

Thomas M McMillan, University of Glasgow, Glasgow, UK

Abstract

For some seven decades, posttraumatic amnesia (PTA) has been viewed by most to be a key indicator of the severity of head injury and a predictor of long-term outcome. Discussed here is a historical introduction, definition of PTA, description of assessment tools, behavior and cognitive function and recovery during PTA, and of relationships between PTA and outcome and the evidence for behavioral interventions that attempt to reduce PTA duration.

Historical Introduction

Early work by Symonds (1928) associated the duration of loss of consciousness and stupor with severity of cerebral injury, and noted that it was common for there to be a period of amnesia after regaining consciousness:

> On regaining his senses he is found to have an amnesia for the period of clouded consciousness. Such patients are often said to have been unconscious during this whole period, but it is important to distinguish between complete unconsciousness or coma and the condition of stupor or clouded consciousness which is characteristic of major contusion.

The concept of posttraumatic amnesia (PTA) was, however, more formally developed by W. Ritchie Russell. While an Assistant Physician in the Royal Edinburgh Hospital, he presented a paper on 'Amnesia Following Head Injuries' to the International Neurological Congress in London in 1935:

> After head injuries accompanied by immediate loss of consciousness, certain disturbances of memory are well known to occur. On full recovery of consciousness, the patient is found to have little or no recollection of events during the period of confusion following the injury.

Russell later moved to Oxford where he developed his interest in head injury through working with casualties in World War II and developed the concept of PTA with which clinicians are so familiar today. In further defining PTA, he cites case examples where individuals could recollect events leading up to the injury early in their confusional state but later have no memory of these events. He later qualified this (Symonds and Russell, 1943) and noted that this endpoint can be followed by a further period of amnesia for hours or days. Russell makes clear that individuals may be able to answer simple questions and yet be disorientated for time and place (Russell, 1935). The emphasis from that time has been on a return of continuous memory for day-to-day events as the endpoint of PTA.

Russell and Nathan (1946) argue that the duration of PTA can be determined long after the injury occurred and that it provides an index of the severity of closed traumatic brain injury (TBI). In support of this, they report data on return to duty in 274 members of the armed services; extrapolating from their table (my analyses) the proportion who returned to duty from hospital (Chi squared = 46.03; $p < .0001$) or to full duties at follow-up (Chi squared = 52.32; $p < .0001$) was greater in those with PTA < 1 day than in those with PTA 1–7 days.

In these early works Russell describes 'islands' of memory during PTA. He describes 'delayed PTA' whereby there is a lucid interval followed by later confusion and amnesia, which he notes to occur more often in the case of gunshot wounds (in about 2.5% of $n = 100$) or relatively little disturbance of consciousness at the time of injury. He links 'islands' of memory to the occurrence of special events such as a visit from a relative, and indicates that they are more likely when confusion appears slight. He notes that behavior during PTA can 'closely approximate to normal.'

Russell also discusses recall of the period in PTA during barbiturate hypnosis, where curiously, one patient remembered aspects of his journey to hospital (some of which were independently verified) that he had not otherwise remembered before; several others remembered no more information under Pentothal. Russell concludes that under Pentothal or occasionally during a lucid period in PTA some can remember aspects around the time of the injury event that they have not remembered before. Also of interest are early attempts by Russell to link preinjury factors such as educational attainment, mental health problems, poor work record and family history (e.g., alcoholism) to outcome, implying a model in which severity of head injury is only one factor and indeed such a model would find current empirical support.

Definition of Posttraumatic Amnesia

PTA as defined by Russell is the duration of disturbance of consciousness following a head injury. This includes coma and a reduction in alertness that is reflected in amnesia for contemporaneous events. Hence, loss of consciousness, disorientation, confusion, and amnesia are included within a definition of PTA. The endpoint of PTA occurs when continuous memory for daily events returns. This avoids erroneously equating PTA with the first memory recalled after a head injury, which may be an 'island' of memory in a sea of amnesia. A formal definition of PTA that equates with the perspective of Russell (1971) is:

> the interval of time between injury and the return of continuous memory for everyday events.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51053-8

Some have argued that it is not appropriate to include coma in the duration of PTA because the relative proportion of time in coma can vary between individuals whose postcoma duration of PTA is the same (Levin et al., 1982). This issue may be of little interest where loss of consciousness is very brief, but where coma is prolonged and the duration of confusion and disorientation is relatively modest, the severity of head injury may be underestimated. A counterargument may be that the total duration from injury to return from orientation and amnesia gives a better estimate of severity of injury and of outcome and this view currently prevails. Hence, most assessment tools define PTA from the onset of loss of consciousness. The endpoint of PTA can be difficult to define where head injury (HI) is extremely severe and anterograde memory impairment continues to be severe. Cases of this kind tend to be relatively few in number and additional assessment of behavior and of daily function may be required.

It is of note that PTA is unlikely to be a valid measure of the severity of penetrating head injury. Here, there can be little or no disturbance of consciousness despite focal damage that results in significant limitations to daily function. In his series of World War II survivors of gunshot head injuries, Russell (1971) observes that 25% had no PTA and in 20% PTA was for less than an hour. Salazar et al. (1986) report that 51% of 342 military casualties with penetrating brain injuries had momentary or no loss of consciousness.

Assessment

Levin et al. (1979) were the first to publish a tool for the prospective assessment of PTA, the Galveston Orientation and Amnesia Test. The original version of the Galveston Orientation and Amnesia Test comprises 10 items; 8 focus on orientation and 2 on anterograde and retrograde memory. The test can be given repeatedly and 'PTA' is defined as a score below 75/100. The Galveston Orientation and Amnesia Test has strong associations with other measures of severity of injury (Glasgow Coma Scale) and disability outcome (Glasgow Outcome Scale). Although simple to administer, the Galveston Orientation and Amnesia Test has been criticized for not including a formal test of anterograde memory, as this can result in an underestimate of PTA (Tate et al., 2006). Artiola i Fortuny et al. (1980) added a test of recall and recognition in the Oxford Test and asked further about first memories after the injury. The end of PTA is indicated on the first day of a perfect score, if there is then a perfect score on two subsequent and consecutive days. The Westmead Post Traumatic Amnesia Scale (Shores et al., 1986) was based on the Oxford Test; it standardized procedures and provided a scoring form. Like the Oxford Test, a perfect score on three consecutive days is required to confirm that PTA has ended. A shortened version, the Revised-Westmead Post Traumatic Amnesia Scale that can be repeated at hourly intervals has been developed for use with less severe head injuries in emergency departments (Ponsford et al., 2004). The Julia Farr Centre PTA Scale (Forrester et al., 1994) also requires a perfect score on three consecutive days for PTA to be considered to be at an end; recent memory is only tested if orientation has returned, and this may not be valid in those with mild TBI (see Recovery and Outcome). One study compared PTA duration in relation to function and behavior after very severe HI on the Westmead, the Modified-Oxford PTA Scale and the Galveston Orientation and Amnesia Test (Tate et al., 2006). The Westmead and the Modified-Oxford PTA Scale differed in terms of the content of recall and recognition tests and the Galveston Orientation and Amnesia Test has no new memory component. Longer PTA durations were found for Westmead and the Modified-Oxford PTA Scale than for the Galveston Orientation and Amnesia Test with overall differences between Westmead/Modified-Oxford PTA Scale being nonsignificant. In a subgroup, PTA duration defined by the Westmead was longer than on the Modified-Oxford PTA Scale, reflecting greater difficulty in the new memory component on the Westmead (Tate et al., 2006). The Orientation-Log is a brief assessment designed for people in rehabilitation and offers the potential for cueing and a range of scores per item (Novack et al., 2000). There are pediatric versions of the Galveston Orientation and Amnesia Test and the Westmead (Ewing-Cobbs et al., 1990; Marossezky et al., 1993). The Westmead may not be valid for children aged below 7 years. The Orientation Group Monitoring System (Corrigan et al., 1988) uses serial ratings by trained ward staff that in addition to orientation and memory includes compliance with therapy and the ability to plan daily activities.

Clearly assessing PTA prospectively is impossible for clinicians who see people later after brain injury in the community. PTA is often not assessed prospectively in hospital, because people with TBI are often admitted to nonspecialist general medical or orthopedic wards. Hence there is a need to consider retrospective assessment of PTA. Indeed, Russell (1971) recommended that the endpoint of PTA is assessed by interview retrospectively. However, there have been few studies comparing retrospective and prospective PTA. One of these compared the assessment of PTA prospectively using the Galveston Orientation and Amnesia Test with a retrospective assessment 3–6 years later using a list of identifiable postinjury events. At reassessment, the assessor was blind to the original Galveston Orientation and Amnesia Test scores (see McMillan et al., 1996). The correlation between prospective and retrospective measures was very high (0.87) and both correlated significantly with several indicators of outcome in daily life. Others have used a protocol for assessment that can be used retrospectively (King et al., 1997). Although prospective measures might be more exact, the need for precision needs to reflect the clinical use of PTA. Clinically and sometimes in research, a range of PTA durations is used to categorize TBI severity, for example as mild, moderate, or severe TBI (see Recovery Severity and Outcome below), in which case there is no need for a precise estimate.

The duration of PTA can be longer in people with severe TBI, if intoxicated at the time of injury (Kaplan and Corrigan, 1992). It is not clear whether intoxication at the time of injury results in a more severe injury; for example, by potentiating effects of the TBI, causing a slower recovery, or a combination of these. The chronicity and severity of alcohol abuse are also likely to be important in relation to outcome. Other factors that may cause or prolong 'PTA-like' memory difficulty during hospital admission include surgery, opioid medication, and anxiety (Kemp et al., 2010).

Severity of TBI, Recovery, and Outcome

PTA is often used to categorize the severity of TBI. The mild, moderate, and severe categories defined by Russell and Smith (1961) were later expanded by Jennet and Teasdale (1981) into very mild (PTA < 5 min), mild (5–60 min), moderate (1–24 h), severe (1–7 days), very severe (1–4 weeks), and extremely severe (>4 weeks). Recovery from PTA often tends to occur in an order that reflects earlier return of longer term autobiographical material; that is with date of birth recovering first and recall of new information recovering last (Leach et al., 2006). Hence, reorientation to family and friends should occur before that for recognition or recall of the names of ward staff. Orientation most often returns in the order person, place, and time, consistent with that found following electroconvulsive therapy for depression (Daniel et al., 1987; Geffen et al., 1991) and irrespective of whether the TBI is mild, moderate, or severe (High et al., 1990). Some inconsistencies between studies in the order of recovery of components of orientation are likely to reflect differences in the items included in categories for 'place and time.' In cases with severe brain injury, recognition memory for new information can often occur prior to re-orientation for time (Tate et al., 2000). Where the brain injury is mild, and PTA is therefore short, reorientation may occur before recovery from amnesia.

Several studies report that PTA predicts late outcome in terms of disability, and that it is superior to other indices of severity of injury such as the Glasgow Coma Scale score or duration of loss of consciousness (Bishara et al., 1992; McMillan et al., 1996).

Cognitive Impairment and Behavior during PTA

One early study reports impairment of general intellect during PTA after severe TBI. Decrements in IQ were 25–40% on average compared to the same participants after recovery from PTA and compared to a separate group of severe TBI's who were not in PTA (Mandleberg, 1975). Impairment in general intellect during PTA was more pronounced for the Wechsler Adult Intelligence Scale Performance IQ (nonverbal) than for verbal IQ. People in PTA tend to show a wider range and more severe cognitive deficits than chronic amnesics or people with severe TBI who are no longer in PTA (Wilson et al., 1992). Most research on cognition and PTA has, however, focused on attention and memory. Severe impairment of declarative memory at recall and recognition and accelerated forgetting is found during PTA (Levin et al., 1988). For some time it was believed that permanent learning and memory largely did not occur during PTA. Later, it became evident that there is a degree of dissociation between motor and verbal learning. For example, Ewert et al. (1989) reported an ability to improve on tests requiring procedural learning (mirror reading, pursuit rotor, and maze tasks) during PTA at a time when deficits in verbal memory were evident. This may reflect neuropathology; the medial temporal areas that serve declarative memory are commonly compromised after severe TBI, whereas the basal ganglia that subserve procedural learning are rarely damaged nor is the occipital cortex that is involved in perceptual priming. A clinical example of this might be the patient with PTA on a ward who learns to find their way to the toilet, but cannot tell you where the toilet is. Deficits in procedural learning tend to be more pronounced in PTA than in chronic amnesics (Wilson et al., 1992). Chronic amnesics are also capable of implicit learning of verbal material (e.g., cannot recall a list of words but can complete the words if given the first syllable such as given 'MEA' for the target, 'meadow') and there is some evidence for implicit learning of verbal material during PTA from a small N study (Glisky and Delaney, 1996). Orientation tends to recover first, including attention required for simple tasks; then recognition, then cued recall and then free recall, with tests that require more effort taking longer to recover (Geffen et al., 1991; Stuss et al., 1999); these findings exemplify the need to incorporate a test of free recall in acute assessment of PTA duration.

Confusion, disorientation, and anterograde amnesia characterize PTA. There is often a lack of insight and sometimes to the extent that the patient may not believe they have had any serious injury. The behaviors that can be associated with this include agitation, irritability, aggression and sometimes violence (e.g., if goal-directed behavior is thwarted such as attempting to leave the ward or when staff is assisting with personal care), and wandering. When seen in the context of poor insight, impaired judgment and amnesia, the individual can simply believe that they are being unreasonably prevented from going about their daily business or even that they are being assaulted or have been imprisoned. In others, with less severe brain injuries behavior can seem normal during PTA. This is exemplified in sports players who sustain a head injury and continue to play, but later that day or the next they may have no memory of the game (Yarnell and Lynch, 1973). If not properly assessed, this can result in a premature return to play with enhanced risk of further injury or poorly planned hospital discharge.

Rehabilitation

Although there is evidence to suggest a better outcome following rehabilitation early after TBI, few studies have looked at treatments specifically for PTA.

Reality orientation is most commonly associated with older adults, where meta-analysis suggests that it can improve orientation in people with dementia, although studies are few in number and small in scale (Woods et al., 2012). Reality orientation was originally developed for war casualties and has been investigated as an intervention to reduce PTA. The Orientation Group Monitoring System incorporates reality orientation in a daily 30 min session in a group format with aims of assessing PTA duration, effects of other interventions, or complications in recovery and potentially as an intervention in itself (Mysiw et al., 1996). As yet, there is no evidence that the Orientation Group Monitoring System is superior to other methods of assessing PTA or that it has therapeutic benefit. The North Star Project in Montreal also considered integration of a reality orientation program in early rehabilitation during PTA. Although a trend toward shorter PTA is reported, this was not statistically different from controls (De Guise et al., 2005). Alderson and Novack (2002) found no difference in recovery of orientation in groups given reorientation sessions daily or

three times a week using the 'Orientation-Log.' Larson et al. (2011) used a three-dimensional virtual reality intervention in an attempt to improve attention early after severe TBI; 60% of their sample of 15 were in PTA. They report improvement in attention in PTA and non-PTA sub-groups; a significant limitation is the absence of a control given that natural recovery is likely to be rapid during this early phase.

There is no strong evidence to support reorientation as an effective technique for reducing PTA duration. More generally, there is as yet no evidence that rehabilitation for confusion and disorientation after TBI is effective and often multidisciplinary neurorehabilitation is recommended to begin after PTA has resolved; hence assessing the endpoint of PTA is clinically important for this reason.

Postal Systems

Richard R John, Columbia University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Postal systems are administratively coordinated communication networks that originated in antiquity, yet remain important today. During their 4000-year history, they have changed significantly, making it hard to generalize about their scale, scope, and accessibility. Until fairly recently, for example, postal systems often conveyed people in addition to information and goods. Most surveys of the world's postal systems are institutional genealogies. Postal systems beget one another in a grand procession of names, places, and dates. Such an approach has the merit of bringing together a wealth of anecdotal material, not easily found elsewhere. Yet, it exaggerates continuity, discourages systematic comparison, and obscures the role of the postal system as an agent of change. This article takes a comparative institutional approach. The world's postal systems are divided into three groups: imperial, corporate, and national. The section on National Postal Systems is subdivided into three parts: early national postal systems, postal reform, and postal systems in the twentieth and twenty-first century. The article concludes with a brief discussion of postal systems and social science, with some suggestions for future research.

Postal systems are administratively coordinated communications networks that originated in antiquity, yet remain important today. During their 4000-year history, they have changed significantly, making it hard to generalize about their scale, scope, and accessibility. Until fairly recently, for example, postal systems often conveyed people in addition to information and goods.

Overview

Most surveys of the world's postal systems are institutional genealogies. Postal systems beget one another in a grand procession of names, places, and dates. Such an approach has the merit of bringing together a wealth of anecdotal material, not easily found elsewhere (Scheele, 1970). Yet, it exaggerates continuity, discourages systematic comparison, and obscures the role of the postal system as an agent of change.

This article takes a comparative institutional approach. The world's postal systems are divided three groups: imperial, corporate, and national. The section on National Postal Systems is subdivided into three parts: origins, postal reform, and recent developments. The article concludes with a brief discussion of postal systems and social science, with suggestions for future research.

Imperial Postal Systems

Imperial postal systems enabled political leaders to conduct diplomacy, plan military campaigns, and oversee routine administration. The most highly developed were those of the Persians and the Romans. The Persian postal system under Emperor Darius (521–486 BCE) employed teams of mounted couriers to transmit clay tablets at 14-mile intervals along a 1600-mile route that stretched from the Tigris River to the Aegean Sea. The Greek historian, Herodotus, praised its speed and regularity: "Neither snow, nor rain, nor heat, nor gloom of night stays these couriers from the swift completion of their appointed rounds."

The Roman postal system, the *cursus publicus*, was established by Emperor Augustus (29 BCE–14 CE) and lasted 500 years. Relays of couriers with horse-drawn carts transmitted official dispatches along with government officials and their baggage. Routes extended throughout the empire and, during military campaigns, to generals in the field. Messages were written on papyrus, parchment, or wax-coated tablets – paper remaining unknown in Europe until after 1000 CE. The relays explain the etymology of 'postal'; it was derived from *positus*, the past participle of *ponere*, 'to place.' Couriers traveled 50 miles a day – a speed rarely exceeded until the nineteenth century.

Access to the *cursus publicus* was largely restricted to government officials. For this reason, some scholars term it a government communication network, and reserve the term postal system for networks open to the general population. Merchants relied on private messengers, seafarers, or friends. Maritime links were particularly important for Christian apostles such as Paul, who used them to send epistles throughout the Mediterranean world.

Corporate Postal Systems

Long after the fall of Rome, imperial postal systems continued to flourish in Asia, South America, and the Middle East. In Europe, however, no comparable institution existed for centuries. When postal systems revived in the 1200s, their organizers were no longer imperial regimes, but corporate bodies – including the University of Paris, the monks of Cluny, and the German butchers' guild.

Corporate postal systems rarely maintained relays of mounted couriers and often lacked the trappings of power. Yet, in several respects, they marked a distinct advance. Many crossed political boundaries, establishing links *between* states as well as *within* them. Few were restricted, like the Roman *cursus publicus*, to government officials. Open access was facilitated by the recent introduction of paper, a light-weight writing medium that was easy to transport. The policy also helped defray costs, since travel was expensive and many corporate postal systems were self-supporting. Henceforth, the primary

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95026-8

constraint for potential postal patrons was financial: postal rates were typically quite high, limiting access to the well-connected and the well-to-do.

Among the most important corporate postal systems were those established by the Italian city-states. By the end of the thirteenth century, couriers linked Venice with Constantinople, and Florence, Genoa, and Siena with northern France. The most enduring was the *Corrieri Bergamaschie* that Amadeo Tasso established in Bergamo, near Milan, in 1290. This institution much impressed the Habsburgs, who, in the 1400s, enlisted the Tasso and Delle Torre families to extend it throughout the Holy Roman Empire.

To oblige the Habsburgs, the families Germanicized their names to Thurn and Taxis. Shortly thereafter, in 1489, Johann von Taxis became the Habsburgs first postmaster. Within the next few years, he and his brother Franz established postal links between the Habsburgs' far-flung domains and Rome, France, and Spain, and opened the service to the general population (Dallmeier, 1977). Couriers carried a distinctive posthorn, an instrument that remains to this day a symbol of the German Deutsche Post. Though the rise of the nation-state greatly restricted its scope, the Thurn and Taxis postal system survived until 1867, when it was bought out by the Prussian government (Behringer, 1990). It has been justly credited with hastening a 'communications revolution' that established the technical preconditions for the emergence of the newspaper in the opening decades of the seventeenth century (Behringer, 2006).

National Postal Systems

Origins

Corporate postal systems stymied the rulers of the emergent nation-states in several ways. Most obviously, they created an unregulated communication channel that threatened political stability. In addition, they deprived rulers of a useful tool with which to monitor the flow of information and ideas. In response, nation-states throughout Europe – led by France and England – established postal systems under tight government control (Coase, 1955).

The French and English postal systems originated, like the imperial postal systems of antiquity, as government communication networks. In France, the founder was Louis XI (1461–83); in England, Henry VIII (1509–47). In both countries, the early 1600s marked a decisive turning point. Within a few decades, both governments granted access to the general population, instituted a monopoly, established a rate structure and delivery schedule, and organized a surveillance mechanism to monitor their subjects' correspondence: the *cabinet noir* in France; the secrets office in England (Robinson, 1948; Vaille, 1946–55). Shortly thereafter, the English government mandated a major rate increase, transforming its postal system into a revenue source, which it would remain until the twentieth century (Daunton, 1985).

Beginning in the 1600s, national postal systems did much to hasten the emergence of the newspaper – at the time, a new form of political communication. This relationship was particularly close in England, British North America, the Netherlands, and Prussia. By permitting the regular transmission of information on current events, postal systems became, in effect, an early broadcast media. Having gained control of the means of communication, governments used it to foster a distinctive worldview. In so doing, they helped forge the national identities that are such a fundamental feature of the modern world (Mueller, 1986).

Nowhere was the relationship of the postal system and the newspaper closer than in the United States. In the 1790s, following the adoption of the federal Constitution, the American government invested its postal system with an educational rationale far more expansive than the fiscal rationale that had previously prevailed. The new mandate, codified in the Post Office Act of 1792, hastened the circulation of newspapers by conveying them at extremely low rates, while enormously expanding the number of localities to which they could be sent (John, 1995). A landmark in postal history, this policy may well have marked for the first time a government that deliberately subsidized the transmission of a particular kind of information to facilitate the circulation of information on public affairs.

By 1828, the American postal system, with almost 8000 post offices, was larger and more geographically extended than any postal system in Europe. At this time, the United States boasted 74 post offices per 100 000 inhabitants; Britain, 17; and France, 4 (John, 1995). Prior to the coming of the railroad and telegraph, the American government had established the preconditions for the disembodied public sphere that French traveler Alexis de Tocqueville would explore so perceptively in *Democracy in America* (1835, 1840).

Postal Reform

Victorian commentators often hailed the postal system of their days as a fundamentally *new* institution that was little older than the railroad and telegraph. For the majority of the population, this was often true. Prior to the 1840s, postal rates remained so high that letter-writing was, in practice, confined to the few. Even in the United States, if a farmer or artisan received anything in the mail, it was more likely to be a newspaper than a letter (Fuller, 1974).

In both Britain and the United States, the high cost of letter postage hastened the establishment of clandestine letter-delivery services in direct violation of the postal monopoly. Following the advent of the railroad in the 1830s, these operations greatly expanded, hastening the major rate reduction known as postal reform.

Postal reform began in Britain, where it was championed by educator Rowland Hill. Hill recognized that high letter rates encouraged illicit mail carriage, and posited that a major reduction would hasten a massive expansion in letter-writing. To buttress his argument, he demonstrated in a famous pamphlet – *Post Office Reform: Its Importance and Practicality* (1837) – that rates bore no relation to expenses. All but a tiny fraction of the cost of delivering a letter, Hill calculated, derived from its *routing* through the system rather than from its *conveyance* from sender to recipient.

Hill prevailed and, in 1840, the British government simplified the rate schedule and reduced the basic letter rate to a penny. Hill styled his reform uniform postage; it was commonly called penny postage. Hill's reform greatly increased mail volume, just as he had predicted. In addition, it hastened the advent of several familiar postal practices – including

mandatory prepayment, mail boxes, and the postage stamp (Daunton, 1985).

Many governments followed Hill's lead. The United States lowered its letter rates in 1847 and 1851; France in 1848. Japan, eager to emulate the best practices in the West, established in 1870 a postal system modeled closely on Britain's (Westney, 1987). Increased mail volume, in conjunction with the advent of the ocean-going steamship, hastened the proliferation of transnational postal treaties. These diplomatic initiatives were regularized in 1874 with the establishment of the Universal Postal Union (UPU), today a branch of the United Nations. The organization of the UPU owed much to Heinrich von Stephan, a gifted postal administrator who had helped to establish a unified German postal system following the creation of the German Empire in 1871.

Closely related to postal reform was the substitution of the railroad for the stagecoach as the preferred mode of conveyance. By the 1830s, stagecoach service had attained a high level of development, especially in Britain and France. Interestingly, Rowland Hill had based his famous cost calculations on the stagecoach, rather than the railroad, which had yet to be widely adopted. Stagecoach speeds often averaged 10 miles an hour, a standard rarely matched since the demise of the *cursus publicus* of imperial Rome. The use of the railroad to convey mail posed various scheduling dilemmas and could increase postal costs; in the United States, for example, it quickly ran the postal system into debt. Yet it proved indispensable, greatly increasing carrying capacity and revolutionizing postal routing. In Britain, the United States, and most industrialized nations, it was long customary to sort the mail onboard moving trains, a practice known as railway mail.

Postal reform ushered in a golden age of letter-writing (Henkin, 2006). In many countries, the exchange of holiday greeting cards became a popular custom. Soldiers' letters emerged, especially in wartime, as a notable mode of literary expression. Though letter-writing would, in the twentieth century, face competition from telephony, the habit persists, and, since the popularization of e-mail, may well be enjoying a revival.

In the decades preceding the First World War, each of the world's leading postal systems – Britain, France, Germany, and the United States – undertook major new responsibilities. Each established a parcel post and instituted a rudimentary banking service known as postal savings. And each, with the exception of the United States, took over the telegraph and telephone, establishing a ministry of Posts, Telegraphs, and Telephones, known in France and elsewhere as the PTT (Bertho, 1981; Perry, 1992; John, 2010). This expansive era in postal history reached its apogee around 1900, when it was common for journalists to hail the postal system as the greatest business in the world (John, 2012). The advent of commercial aviation in many countries, including the United States, owed much to the generous mail contracts that postal administrators awarded airline firms, a relationship that underscored the longstanding role of the postal system in hastening transportation innovations.

Recent Developments

In both the developed and the developing world, postal systems today remain indispensable elements of the information infrastructure (Sinclair, 1984). In the past few decades, however, much has changed. Beginning around 1970, rapid changes in communications technology led many governments to reevaluate the union of the postal system, the telegraph, the telephone. Deregulation followed. In Britain, the breakup came in 1981; in France, in 1991.

The Internet poses a further challenge, yet, in a sense, it is nothing new. For a century and a half, postal systems have coexisted with earlier modes of electric communications. The United States today is the originator not only of the Internet, but also of 40% of the entire world's mail. A century ago, pundits routinely predicted that telegraphy would soon render mail delivery obsolete. Today telegraphy has been everywhere supplanted, while postal systems persist.

Additional challenges stem from the emergence of new competitors – DHL in Europe; Federal Express and UPS in the United States. Express firms rely on improvements in air travel to compete head-on with the national postal systems in key high-value markets. In response, many governments have reexamined – and, in several cases, narrowed – the scope of the postal monopoly (Campbell, 1994).

Postal administrators have met these challenges in various ways. Many have transformed national postal systems into public corporations, a transformation that is sometimes called privatization. If this trend continues, postal systems in the next century may share less with the national postal systems out of which they evolved than the corporate postal systems of medieval Europe. The French postal system – known today as La Poste – has been a publicly traded corporation for over 30 years (Le Roux, 2002). The British postal system, Royal Mail, has aggressively sought new markets (Campbell-Smith, 2012). So, too, has the Deutsche Post, which issued its first securities in 2000, and the U.S. Postal Service, which has not been a government department since 1970 and no longer receives a government subsidy.

Postal Systems and Social Science

Scholars agree that the printing press was an agent of change. Only recently, however, have postal systems been studied in a similar way. The last edition of the *International Encyclopedia of the Social Sciences* (1968) contained no entry on the postal system, and no references to it in the index.

The rise of the new institutionalism in history, sociology, and political science bodes well for postal studies. So too does the continuing vogue for French literary theory, with its focus on the complexity of the communication process (Siehart, 1993). Recent developments in information technology promise further insights, offering new perspectives on modes of communication that are seemingly being displaced. For postal scholars, Hegel's dictum holds true: the owl of Minerva flies at dusk.

Research opportunities abound. Comparative data remains scarce, especially for the period prior to 1840. Without it, it is hard to frame credible generalizations about what postal systems did and how they worked. Topics that invite exploration include the development and significance of scheduling; censorship and surveillance; postal privacy; communication networks and the rise of nationalism; challenges to the postal monopoly; changing rationales for postal systems; and the shifting meaning of the equal access ideal.

Postcolonial Geography

Jane M Jacobs, Yale-NUS College, Singapore

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article traces the emergence of postcolonial geography in the 1980s and the intellectual contributions it has made since, including reference to key thinkers. It discusses the relationship with postcolonial studies more generally and outlines the distinct lines of inquiry taken in postcolonial geography, namely: historical geography revisions of colonialism; contemporary studies of the geographies of postcolonial formations and expressions; and critiques of Western-centric geographical theory building and empirical scholarship. It also discusses the methodological legacies of postcolonial geography approaches.

The contemporary geographical scholarship that describes itself as 'postcolonial' has much in common with other parts of the social sciences and humanities that use this term to describe their approach and matters of concern. That said, there are certain historical connections between geography and the making of empires, which add an imperative to the way geographers engage with postcolonial thought and phenomena. Pragmatic geographies of surveying and mapping were the frontier technologies of imperial exploration and the operations that brought distant territories under the control of metropolitan centers as colonies. As historian Edward Said noted in *Culture and Imperialism* (1993: p. 271), imperialism is "an act of geographical violence through which virtually every space in the world is explored, charted, and finally brought under control." The imperial expansions of eighteenth and nineteenth century Europe appropriated the resources of other peoples and lands. That material interest was motorized by a complex value system, which made audacious and often-violent appropriations make perfect sense to the colonizers. Ideas about the racial hierarchy of humankind placed Caucasians over and above all others and enabled European colonizers to assume a racial superiority and civilizational worth that legitimated their imperialism. The modern discipline of geography lives uneasily with this past and in the 1990s that ambivalence offered a moral compass for the emergence of postcolonial geography.

Original Scope of Postcolonial Geography

Those geographies described as 'postcolonial' use the term in a range of ways, as is the case in other parts of the social sciences and humanities. First, it is used to describe the formal political circumstance of a nation or political entity becoming independent from colonial rule or an imperial force. Second, the term is used to describe a set of social, cultural, and political formations that come into being because of, and usually in opposition to, colonization. Such formations may temporally precede a formal state of postcolonial independence, but they may also emerge well after that independence is realized due to the lingering after effects of colonialism. Third, the term is often used to describe research that is informed by postcolonial theory and which applies its analytical tools to, say, race relations, processes of development, subaltern or nativist intellectual and political formations, or creative expressions. Postcolonial geographies may be either historical or contemporary in focus. For example, a persistent interest of more historically focused postcolonial geographers has been revisiting the site of colonialism and offering revisionist accounts. Another body of work examines contemporary conditions of decolonization, even amid the insistent presence of imperial logics. Yet more work looks at the emergence of hybridized systems that are both dependent upon lingering colonial logics but operate subversively. Many have questioned the 'post' of postcolonialism. Postcolonial formations remain complexly entangled in their colonial pasts, just as they are constantly negotiating various kinds of neocolonialism, be it in the form of geopolitical influence, cultural effect, or economic leverage. The persistence of various kinds of colonialism has led scholars to note that the term postcolonialism is prematurely celebratory.

While having much in common with other variants of postcolonial studies, the distinguishing feature of postcolonial geography is that the research emphasis is on the spatial logics and expressions of colonial and postcolonial phenomena (Sharp, 2009). Historically inflected scholarship within postcolonial geography offers a critical reappraisal of the spatialized forms of knowledge, political systems, and social identities authorized under colonialism. In 1993, Livingstone (1993) published an account of the geographical tradition, within which he paid particular attention to the relationship between European geography, race, and empire. Driver (1992, 2000) has similarly 'unmasked' geography's disciplinary relationship to European colonization. By demonstrating the way geographical knowledges framed other worlds within imperial projects, this article has empirically thickened the analytic framework set by Edward Said's landmark contribution *Orientalism* (1978). One particular geographical knowledge form has come under specific scrutiny: the map, and its associated practical sciences of survey and cartography. This imperial knowledge system made meaningful both peoples and lands that, from a Eurocentric worldview, were so radically different that ofttimes they could only be understood as 'savages' or 'wastelands.' Harley's (1988) reappraisal of cartographic practices and colonialism seeded an ongoing scholarship on cartography and power. More recent scholarship has

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72040-X

examined the relationship between new technologies of mapping such as geographic information system and new nonterritorial styles of imperialism. Others have turned their attention to how digital mapping technologies have been used in the counter cartographies of postcolonial nation building (Radcliffe, 2009) or struggles by indigenous groups to have their land rights and cultural sites recognized (Dunn, 2007).

The 1990s to the early 2000s offered over a decade of sustained research in the area of postcolonial geography, the full breadth of which is showcased in a number of edited collections (Godlewska and Smith, 1994; Bell et al., 1995; Blunt and McEwan, 2002). Some significant lines of inquiry are worth mentioning. Geographers became interested in the ways in which the largely racial logics of differentiation that underscored colonialism were intersected with other axes of difference, such as gender (Blunt and Rose, 1994; Phillips, 1997). Other geographers denaturalized the racial category of whiteness itself, looking at the ways in which it generated, and held in place, assumptions about authority and civility that shaped landscapes, past, and present (Bonnett, 2000; Shaw, 2007). Geographers also attended to the ways the built environment reflected colonial values, imperial nostalgias, and modernizing aspirations (Smith, 1992; Jacobs, 1996; Yeoh, 1997; Driver and Gilbert, 1999; Jazeel, 2013). Colonial cities were important sites in the transfer of modern, European values to new worlds and functioned as important centers of power for administering colonized people and resources. In these cities, town-planning ordinances about cleanliness and sanitation became the mechanism through which colonial assumptions about racial difference were translated into on-the-ground technologies of segregation and exclusion.

Postcolonial Geography Revisions

By 2003, the editors of a special issue of the *Singapore Journal of Tropical Geography* on postcolonial geographies could conclude that the subfield was 'rich and contentious.' One contention came from the emphasis on historical examples, as well as the reliance on interpretative approaches to representational and discursive data. This bias was unsurprising given that geographers took inspiration from a wider field of postcolonial studies, which was grounded in the fields of literature and history. In 2003, Jennifer Robinson called for geographers to expand the scope of critical scholarship bequeathed by postcolonial geography. She took inspiration from an argument about 'postcolonial modernity' proposed by the historian and social theorist Dipesh Chakrabarty in his *Provincializing Europe* (2001). Chakrabarty pointed out that much of what is said about the experience of postcolonial modernity is constructed in and through European social scientific concepts. As Chakrabarty puts it: "European thought is at once both indispensable and inadequate in helping us to think through the experiences of political modernity in non-Western nations." Given that many of the core analytical tools of the so-called universal social science were grounded in the specific experience of Europe, the next phase of the postcolonial social scientific project became one of 'provincializing Europe': exploring how its social scientific thought 'may be renewed from and for the margins' (Chakrabarty, 2000: p.16).

Robinson's plea set postcolonial geography on a new course, which might be better described as an 'after-the-West geography.' She called for a 'cosmopolitan' geographical scholarship that looked beyond the West, both in social theoretical terms as well as in terms of practical knowledges and actions of world building. As Robinson (2003: p. 273) puts it: "A geography whose intellectual vision is limited to the concerns and perspectives of the richest countries in the world has little hope of effectively participating in the debates that will matter in the twenty-first century." Robinson gave empirical flesh to this proposition by thinking about urbanization in non-Western contexts. She argued that cities in such contexts were often compared negatively to models of urbanization generated from the circumstances of Western cities. She called upon geographers to generate revised theories of urbanization that took as their starting point the processes exhibited in the many other 'ordinary cities' (Robinson, 2006). In a similar vein, other geographers began to apply this after-the-West version of postcolonial scholarship to existing theories of economic and political development. Using such a lens meant that non-Western experiences of development were not simply seen as slower or lesser or mimetic versions of the West, but offering alternative models of what modernity and development might be (McEwan, 2009; Pollard et al., 2011). These new directions in postcolonial geography had considerable intellectual overlap with what has come to be known as postdevelopment studies (Escobar, 1995; McFarlane, 2006; Sidaway, 2007).

Legacies and New Directions

Postcolonial geographical perspectives have resulted in important methodological legacies. First, there is a new self-reflexivity among geographers with respect to how they construct their geographies and the power differentials that exist when they work across cultural or development divides. Second, and relatedly, there is a new awareness of the need to reflect upon the origins of apparently neutral or universal explanatory frameworks drawn upon in geographical explanations. Third, there is a commitment to creating geographies that readjust colonial or neocolonial structures of authorization with respect to who speaks and with what authority. For example, geographers have used multiple authorship to this end (Huggins et al., 1995), as well as various models of participatory or action research (Pain and Kindon, 2007). Fourth, there has been renewed and revised application of comparative methods in the discipline (Robinson, 2011). This new comparativism is distinct from earlier methods, and instates a cosmopolitanism necessary to the construction of geographical knowledges in an era of transnational movements and the emergence of non-Western centers of power.

Has the time for postcolonial geographies passed? Many of the methodological and theoretical developments bequeathed by a postcolonial approach will leave a permanent legacy. Furthermore, there are many current events that ensure ongoing relevance for a postcolonial geography. The transnational logics of contemporary times leads all too easily to

conclusions that the world is succumbing to the homogenizing force of globalization. That suffocating fact can be challenged by adhering to a postcolonial perspective, which is attuned to alternative modernities and trajectories of development. Furthermore, global connectivity in communication and travel has led to new opportunities for transnational solidarities among groups seeking postcolonial recognition of their rights, generating a still emergent era of 'global indigeneity' (Sidaway et al., 2014). And there are many colonial presents. Some of them are starkly territorial, as Gregory (2004) shows with respect to the contemporary geopolitics of the Middle East, which still draws sustenance from persistent orientalisms. Others are variations of seemingly familiar developmental expansions, such as the effects of Rising Asia, including China's presence in Africa or the South China Sea (Mohan and Power, 2009; Agnew, 2012; Anand, 2012; Raghuram et al., 2014). Yet others operate in and through the logic of culture, such as the imperialism of the English language, which creates profound challenges for creating fully cosmopolitan geographies inclusive of other knowledges and voices (Kitchen, 2005). Finally, the planetary ill effects of humankind on the environment, what has been dubbed the age of the Anthropocene, offer new imperatives for postcolonial geographies (Jackson, 2014; Sidaway et al., 2014). This developing 'planetary' circumstance is calling various social institutions (be they nations, organizations, or ethnically defined groups) into new relationships of responsibility and accountability with respect to the environment, resources, and productivity.

Postcolonial Law

Abstract

Postcolonialism and the problems associated with postcolonial law are today more widely recognized than ever before among scholars, political philosophers, and legal practitioners. However, the terms of the conversation have shifted since postcolonial theory first emerged as a new arena of critical scholarship. Today, postcolonial theory addresses the oppression of all communities historically treated as racially and ethnically inferior to Europeans, whether or not these communities self-identify as 'indigenous' or think of themselves as formerly colonized. This article explores the challenges presented by postcolonial law and related analyses of legal orientalism in the twenty-first century. Acknowledging the postcolonial dimensions of legal exchange between the global North and global South demands a rethinking of the prevailing Eurocentric, state-bound understanding of what constitutes law in the current global era.

Postcolonial Law in the Twenty-First Century

Postcolonialism and the problems associated with postcolonial law are today more widely recognized than ever before among scholars, political philosophers, and legal practitioners. However, the terms of the conversation have shifted to more aptly apply to current global geopolitical realities. Whereas the language of earlier postcolonial theorists focused on the dialectic between colonizing nations and the colonized, contemporary scholars talk in terms of the relations between what is commonly referred to as the global North and global South. This shift in terminology expands the lens of analysis from state-centered law in the context of specific national colonial enterprises to a more global post-westphalian worldview that takes into account transnational, regional, and state interrelations (Falk, 1998). It also opens up the conversation to include the oppression of all communities historically treated as racially and ethnically inferior to Europeans, whether or not these communities self-identify as 'indigenous' or think of themselves as formerly colonized.

Contemporary scholars of postcolonial law draw upon an intellectual legacy that traces back to postcolonial studies that emerged in the 1980s to talk about postcolonial law in a more encompassing way. These scholars are interested in the underlying orientalist assumptions in national and international law that affirm essentialized constructions of cultural difference (Ruskola, 2002; Falk, 2009; Pahuja, 2011), and inform many countries' flawed polices of multiculturalism (Bhandar, 2009; Marés, 2007). Importantly, what links the legacy of postcolonial studies to contemporary analyses of legal orientalism is a central focus on the endurance of historically structured racial and ethnic divides between Western and non-Western societies despite a growing appreciation of their respective interdependencies.

Postcolonial theory is largely associated with a rethinking of a dominant European historiography that places the West at the center of the world. Associated with South Asian scholarship, subaltern and literary studies as well as analyses of resistance, postcolonial theory emerged out of the global South in the 1980s and gained an increasing presence in Anglo-European universities (Prakash, 1990, 1992; O'Hanlon and Washbrook, 1992; Chakrabarty, 1992). With the proliferation of postcolonial research, there was, and remains, much debate over the meaning and scope of postcolonial terminology and its political agenda (see Williams and Chrisman, 1994; Schwarz and Ray, 2000; Loomba, 2005; Mongia, 2009). Despite these ongoing deliberations, it is helpful to turn to the most significant implications of a postcolonial perspective, which mark it as distinctly different from, yet complementary to, other critical investigations associated with critical race theory, critical legal theory, and poststructuralist and feminist theoretical perspectives. This process will help to flesh out the contours of postcolonial studies and, at the same time, underscore its intellectual lineage and relevance to contemporary legal analyses.

Below I discuss some of the insights postcolonial theory brings to bear on an understanding of legal orientalism in contemporary legal processes. This is most notably achieved through the theoretical insights of Edward Said, who was a leading figure in postcolonial criticism and whose book *Orientalism* (1978) established a long trajectory of critical thinking about the subjugation of non-Western peoples. Specifically, postcolonial theory reveals the violence and the technologies of power involved in understanding concepts such as modernity and capitalism as well as contemporary state and trans-state nationalisms (Baxi, 2000; Spivak, 1999; Darian-Smith and Fitzpatrick, 1999; Comaroff and Comaroff, 2006). Moreover, postcolonial theory provides the intellectual bridge linking historical colonial injustices to contemporary global racial injustices and asymmetries of power between a global North and global South. In short, postcolonial theory provides the intellectual platform from which to identify, analyze, and assess what is encompassed in the wider geopolitical framing of the term 'postcolonial law' in the twenty-first century.

Defining a 'Postcolonial' Perspective

Postcolonial theory acknowledges and recovers the ongoing significance of colonized peoples in shaping the epistemologies, philosophies, practices, and shifting identities of dominant and taken-for-granted Western subjects and subjectivities (Santos, 2007). Postcolonial scholars bring to the foreground the cultural and psychological relations between the former

colonized and colonizers, whom, they argue, cannot be understood except in conjunction with each other (Gandhi, 1998). Postcolonial theorists do not claim that colonialism was experienced in the same way under different regimes, just as they recognize that today colonialism operates in very different ways from its earlier configurations. Nonetheless, while paying attention to the details of specific contexts, postcolonial scholars agree that in order to understand all contemporary histories of peoples and places, irrespective of whether there historically existed in any given site an explicit colonial regime, it is important to remain aware of the enduring presence of discourses that posit 'civilized,' 'progressive,' and 'lawful' Europeans against 'barbaric,' 'static,' and 'lawless' native populations.

According to these scholars, colonial assumptions of Western superiority endure across time and undermine contemporary attempts to build more inclusive multicultural societies. This is because categories of racial difference were used to varying degrees by colonial governments to gain power and control over locally subjugated peoples (Stoler, 1989; Dirks, 1986). Today, despite claims of increasing acceptance of the concept of multiculturalism and cultural diversity, racial categories, and racialized differences continue to exist, though often in less overt manifestations (Goldberg, 2008; Lentin and Titley, 2011). Moreover, according to many postcolonial theorists, these boundaries of difference are insurmountable, because the psychological intersubjectivity between former colonizers and colonized people constantly invites re-representations of difference (see Fitzpatrick, 1999).

Drawing on a variety of theoretical perspectives – including an Hegelian master/slave dialectic, phenomenological essentialism, and psychoanalytical insights gleaned from Franz Fanon and Jacques Lacan – postcolonial theorists such as Homi Bhabha, Gayatri Spivak, and Benita Parry bring to the fore complex understandings of how oppressed peoples resist and seek empowerment. In recognizing processes of mutual desire and negation between the 'master' and 'slave,' postcolonial scholars have had to grapple with alternative historical narratives and identities other than those conventionally supplied by the West (Trivedi and Mukherjee, 1996). The irony is that the process of self-determination by peoples formerly colonized requires the adoption of European knowledge, including concepts such as 'progress,' 'development,' 'individualism,' and what it means to be human. It also means the use of Western forms of government, state-building, and perhaps most importantly of all, law. Thus, according to a postcolonial perspective, all assertions of freedom and self-awareness require elements of mimicry and voyeurism. As Douglas Robinson has noted:

> Postcolonial or subaltern scholars claim it is at once essential and impossible to forge a 'new' postcolonial identity: *essential*, because those colonial constructs were at once alien and negative, because they came from the outside and destroyed much of value in the indigenous cultures, and because an effective postcolonial politics requires the development of more positive indigenous visions: but also *impossible*, because colonial discourse continues to inform even these postcolonial attempts to break free of it, and tends to condition even the imagination of a 'new' (postcolonial) identity along 'old' (colonial) lines (Robinson, 1997: 19–20).

A prominent postcolonial theorist, Dipesh Chakrabarty, has responded to the ironies of alterity by calling for the 'provincializing,' or decentering, of Europe and European epistemological knowledge. Chakrabarty (and others) argue that non-Western knowledge has been historically ignored and precluded from historiographical accounts of humanist understanding and intellectual endeavor (Chakrabarty, 1992, 2000). In an effort to critique "the 'Europe' that modern imperialism and (third world) nationalism have, by their collaborative venture and violence, made universal," Chakrabarty urges scholars "to write into the history of modernity the ambivalences, contradictions, the use of force, and the tragedies and the ironies that attend it" (Chakrabarty, 1992: 20–21).

Postcolonial Law

Nowhere in the histories of modernity has the 'use of force, and the tragedies and the ironies that attend it' been as obvious as they are in the context of legal engagement. European law, in a variety of ways, was the formal mechanism and institutional frame through which colonial governments oppressed and controlled indigenous peoples. Of course, there are many varieties of imposition and reception of law, a few even categorized as voluntary. In some cases, such as in Africa (Mamdani, 1996), this involved co-opting native chiefs and traditional procedures of arbitration and dispute resolution. In other cases, such as Australia, the British declared the continent *terra nullius* or vacant, and on the basis that native populations were thought to be less than human, they were deemed to have no law at all (Behrendt, 2003). As a result, traditional local methods of peacekeeping were often overlooked or deliberately obliterated. Law – emblematic of European rationalism, individual property rights, and sovereign state authority – provided the justification for domination and exploitation based on racial, ethnic, or religious inferiority.

It is impossible to separate colonial from postcolonial law because each developed in collaboration and conjunction against and through each other (Merry, 2004; Darian-Smith, 1996). Hence it can be said that nineteenth century metropolises such as New York, Paris, and London were always connected with and influenced by their nation's colonial peripheries, be these geographically distanced outposts beyond state boundaries or socially and politically isolated enclaves (such as native reservations) within it. Similarly, colonial outposts were intimately connected back to their colonizing oppressors. In short, colonies emerged over time as intricately entangled hybrid societies incorporating European and non-European sensibilities. Hence the decolonized countries of the post-1945 era – such as India, Algeria, South Africa, and the Philippines – could not entirely excise their Euro-American colonial legacies. Moreover, these newly independent nations had little choice but to adopt European forms of state building and the institutions, bureaucracies, and constitutions of their former masters. Such formalities were necessary in order for new states to declare themselves 'liberal' and 'modern' and to participate in national and international political and economic organizations such as the United Nations. The rule of law exemplifies the postcolonial dilemma that required – and still requires – self-

determining nations to mimic and adopt Euro-American legal concepts and structures.

Globalization and Postcolonial Law

Prevailing discussions about law and globalization epitomize the ironies presented by postcolonial law. For instance, The United Nations, World Bank, International Monetary Fund, and other international legal arrangements all require that in order for a country to participate in the global political economy, it must demonstrate commitment to, and adherence with, the foundational values of Western law (Halliday and Osinky, 2006: 455–456). In a postcolonial world, just as in the colonial situation, there are always ongoing modifications and appropriations between all interacting communities. One only has to think of human rights to appreciate the extent to which its apparently universal application has to be constantly translated and modified to fit the social, political, and economic values of particular peoples living in localized places (Merry, 2006; Sarat, 2001). Similarly, Euro-American law is not entirely impervious to the influence of laws emanating from the global South, as illustrated by the adoption of the United Nations Declaration on the Rights of Indigenous Peoples in 2007. That being said, the global dominance of Euro-American law in the early decades of the twenty-first century is not easily destabilized. And as a result, Euro-American law structurally institutionalizes the enduring asymmetries of power between the global South and global North and pervasively fashions and legitimates certain legal practices, meanings, and imaginations that have their origins in the global North (Darian-Smith, 2000).

Within much scholarship there lingers a deeply embedded assumption of the global North's legal superiority vis-à-vis the rest of the world (Darian-Smith, 2013). This is evidenced by a majority of United States and European scholars continuing to treat the rule of law as a discrete entity and not as a dynamic product of historically contested and culturally informed colonial–postcolonial interactions. Thus well into the twenty-first century, in arguments both for and against the enduring significance of the nation-state in the increasing context of globalization, the dominance of Western legalism is taken as a given. As a result, analysts of law tend to look only at the privileged domains of legal interaction among lawyers, judges, businesspeople, and entrepreneurs, and to ignore the perspectives of ordinary people whose culturally informed normative understandings of law may be very different (Ewick and Silbey, 1998). In short, scholars should not ignore the 'contribution of the masses' (Rajagopal, 2003: 402). We need to be concerned with how globalization affects peoples in different ways, and studies should include both the small, cosmopolitan, plane-hopping legal elite *and* the millions of peoples from various classes, cultures, ethnicities, and religions whose understanding of law may appear to those embedded in a Western legal heritage as 'traditional' or 'backward.'

Legal Orientalism and Postcolonial Law

Postcolonial law requires that scholars and practitioners come to terms with the fact that there is no universal legal code and no such thing as pure legal objectivity, but rather a complex overlapping plurality of legal systems and legal meanings. If this view was to take hold, the naturalized centrality and superiority of a Euro-American legal perspective would be dislodged and, borrowing Chakrabarty's terminology discussed above, would become necessarily 'provincialized.' However, given the relations between law, capitalism, and a global political economy, it is perhaps not surprising that Western legal scholarship has largely ignored (some would argue deliberately) the challenging presence of postcolonial law. In an attempt to move beyond this deadlock, some scholars are coming at the problem of legal plurality by talking about the issue of legal orientalism. These scholars take a long historical view in arguing that legal orientalism has shaped the development of modern Euro-American law from the sixteenth century to the present (Ruskola, 2002; Anghie, 2006; Falk, 2009: 39–54). This argument forces us to think about how racial and cultural biases continue to inform globally dominant legal concepts and assumptions of Western legal superiority, and may in turn open up ways to challenge or resist these dominant legal understandings of the world (Santos and Rodriguez-Gavarito, 2005).

What is legal orientalism? As mentioned above, the concept of legal orientalism draws expressly upon the work of Edward Said, a leading figure in postcolonial theory. Said coined the word 'orientalism' to refer to the ways European societies throughout the nineteenth century constructed their identity and self-understanding through imagining their difference from the Arab and Muslim world (Said, 1978, 1993). Essential in this process was the West's stereotyping of the Orient, which included a range of Eastern cultures that included the Middle East as well as China, Japan, and South Asia. Orientalist discourses emanating from Europe were not exactly the same as those emanating from the United States because they were usually directed toward the Middle East and China, while in the United States orientalist rhetoric was usually directed to the Philippines and targets closer to home (Little, 2008; Brody, 2010; Francavigilia, 2011). These differences typically correlated with a country's imperial and colonial interests and often changed over time. However, what united these various forms of orientalist rhetoric and material practice was the assumed oppositional relations between an exoticized Orient and a civilized Occident.

Typically nineteenth century orientalist discourses about the East were negative and reinforced a presumed hierarchy of Western superiority and Eastern inferiority. However, this was not always the case, as seventeenth and eighteenth centuries Enlightenment philosophers and missionary Jesuits often praised Chinese people for their ingenuity and skill (see Gregory, 2003; Mungello, 2009). However, by the nineteenth century European attitudes about Asian peoples had crystallized into derogatory stereotypes (Ruskola, 2002). Europeans promoted themselves as modern, rational, moral, and lawful in contrast to a projection of Eastern societies as premodern, irrational, immoral, and lawless. Hence, at the same time that commentators such as Alexis de Toqueville were remarking upon the emphasis given to law in the United States in the 1830s, historians and social theorists were pointing to the lack of law in countries such as China, which was essentially viewed as a backward, 'stagnant' society in which lawlessness reigned

(Ruskola, 2002: 181–187, 213–215). But as insisted upon by Said, this did not mean that the "Orient was essentially an idea, or a creation with no corresponding reality" (Said, 1978: 5). Rather, "The Orient is an integral part of European *material* civilization and culture … with supporting institutions, vocabulary, scholarship, imagery, doctrines, even colonial bureaucracies and colonial styles" (Said, 1978: 2).

Legal orientalism served a variety of purposes. The most obvious of these was that it helped confirm on the world stage the marginality of the East and the centrality of the imperial West. European and American scholars argued that Eastern jurisprudential traditions were based on custom, ritual, and religion in contrast to the so-called rational and scientific legal systems of modern Western nations. Declaring non-Western legal systems inferior helped to justify European law and culture as a superior civilization, worthy of world leadership and dominance. Orientalist rhetoric also provided the rationale for Western nations to marginalize Asian peoples within their domestic jurisdictions. For instance, in the United States orientalist rhetoric provided the basis for the Chinese Exclusion Act (1882). This act suspended Chinese immigration into the country and prevented those Chinese people already living in the United States from ever being granted citizenship. Under the act, it was argued that Chinese people were nonlegal subjects because they were incapable of understanding American law and so deserved to be excluded from the new republic (Park, 2004; Ruskola, 2002: 215–217).

Postcolonial legal scholars argue that the oppositional rhetoric between Eastern and Western legal traditions was essential for the development of modern Euro-American law. In other words, European law emerged historically through a perceived difference from non-Western legal concepts. According to the sociolegal scholar Duncan Kennedy, international law must be understood in relation to "a distinction between the West and the rest of the world, and the role of that distinction in the generation of doctrines, institutions and state practices" (Kennedy, 1997: 748). This perceived difference helped shape the international legal system, which required the 'invention of legal primitivism' to legitimate the West's universal aspirations (Gathii, 1998; Bowden, 2005; Anghie, 2006; Wilf, 2009).

If one accepts this argument, then it follows that Western law has orientalist assumptions historically built into its language, structure, and procedures. This suggests that contemporary Euro-American law, and the international legal system on which it is built, remains to this day intrinsically and pervasively cultural and racially biased (see Pahuja, 2011; Westra, 2011). In short, legal orientalism endures in twenty-first century international law and global legal relations (see Otto, 1996; Falk, 2009; Haldar, 2007). Legal orientalism continues to fuel assumptions about the global North's legal superiority over the global South and has been deployed in a range of national and international legal forums such as asylum and refugee claims (Akram, 2000). Moreover, legal orientalism is evident in the ways the global North interprets law in the Middle East, particularly in the wake of the events of 9/11, and how Western nations view law in China, Africa, and Latin America. However, as the international legal scholar Teemu Ruskola remarks, the point of recognizing the presence of contemporary legal orientalism is not to overcome our cultural biases – an impossible task – but rather to ask why certain orientalist images of law developed, why they continue to resonate in the contemporary world, and what can be done to dilute these negative stereotypes that undermine international law and prevent sincere global dialogue and creative legal collaboration (Ruskola, 2002: 222).

One thing that is certain – whether one frames asymmetrical power relations in terms of postcolonial law or legal orientalism – is the need to move past a modernist hierarchy of legal authority based on simplistic binaries of rational versus nonrational and civilized versus uncivilized legal systems. De-orientalizing the twenty-first century's normative global order and stereotyped legal divides is seen, by some scholars and analysts at least, as ultimately necessary for the stability and peace of global, international, national, regional, and local relations (Santos, 2007; Onuma, 2010). As the Nigerian legal scholar Ikechi Mgbeoji has eloquently stated, "the North and South are mutually vulnerable, sharing a common destiny, which cannot be realized unless notions of a civilized self and barbaric other are abandoned" (Mgbeoji, 2008: 152).

Postcolonial insights offer some insights as to how to get past historically structured racialized divides between peoples and communities. The political theorist Duncan Ivison in his book *Postcolonial Liberalism* (2002) argues for the need to create a "genuine 'multilogue' not just between the state and indigenous peoples, but between them and other cultural and national groups as well" (Ivison, 2002: 163). In his arguing that indigenous peoples can make considerable contributions in the thinking of how to build more inclusive societies, Ivison notes that this will take time and a firm commitment to "the ideal of a political order in which different national groups, with different modes of belonging and different conceptions of the good and the right, nevertheless share a willingness to live under political arrangements that reflect this plurality" (Ivison, 2002: 166). Ivison's argument underscores the political challenge of a postcolonial perspective with respect to law. In order for there to be "a context-sensitive and embedded form of public dialogue and deliberation" (Ivison, 2002: 163), we must first rethink the prevailing Eurocentric, state-bound understanding of what constitutes law. In other words, embracing postcolonial law and coming to terms with its deeply problematic histories of colonial oppression is perhaps the first step in a process toward building a global legal future that is more inclusive, responsible, and equitable.

Postcolonial Science Studies

Abstract

During the past 20 years, postcolonial approaches have emerged to explain the distribution and local adaptation of science, technology, and medicine around the world. Such studies contest European and North American hegemony in science, situating and thereby dismantling global or universal claims. Critical postcolonial analysis should be distinguished from anodyne talk of 'global flows' and from actor-network theory, which avoids discussion of power differences and structural inequalities. This article explains the origins of postcolonial science studies, describes their various forms and functions, and suggests future elaboration of this sort of critique.

Postcolonial Science Studies

Since the late 1980s, some postcolonial attitudes, or at least postcolonial premises, have slowly worked their way into science and technology studies, though their presence often is hidden or even denied. Studies that contest European and North American hegemony in science, situating and thereby dismantling global or universal claims, represent what might be called the postcolonial turn. Recognition of creditable knowledge making beyond North Atlantic shores constitutes a postcolonial approach. So too does the emphasis on hybridity, heterogeneity, and indeterminacy in what once appeared to be sovereign, uncontaminated categories. A postcolonial orientation directs attention to the complexities of relations in any contact zone. It re-examines the terrain that empire has tilled across the world, showing that dominance is never absolute – that imperial or authoritative knowledge, despite colonial fantasy and amour propre, must always adapt to local conditions, mix with other traditions, and incorporate difference. In this sense, the argument that we have never truly been modern (Latour, 1993) is implicitly postcolonial. Thus an analysis that deconstructs imperial binaries such as nature–culture, modern–traditional, global–local builds on a postcolonial, or decolonizing, platform. Even if explicit recourse to postcolonial theory remains rare in science and technology studies, a postcolonial sensibility has infiltrated its critical scholarship.

'Postcolonial,' however, is a tricky word. It can signify a simple temporal distinction – what comes after the colonial – or a complicated analytic framework. Even more confusing, postcolonial analysis implies the opposite of postcolonial temporality, as it suggests the persistence of the complexly refigured colonial: that the colonial as a sort of contact zone, or place where differences meet, is always, and everywhere, with us. In this sense, the 'colonial' now needs to be deconstructed as a site of contestation, difference, and unstable hybridity – not the old colonial wish fulfillment of dominance and submission, of polar opposites. The inability to distinguish the temporal (and perhaps meretricious) postcolonial from the critical, wide-ranging analytic postcolonial leads to perplexity and bafflement even among experienced scholars (not to mention copy editors with an aversion to hyphens). Perhaps we should substitute 'postindependence,' or 'decolonized,' or 'national,' for the temporal postcolonial. But while this may allay confusion, it would be regrettable if critical postcolonial analysis were to sever some of its historical ties, attenuated as they are, to the earlier liberatory projects. Instead, we should remember that as shape-changing empire endures, the need to decolonize knowledge, or to deflate its colonial puffery, never ends.

Postcolonial studies of the spread and refiguring of European science and biomedicine offer an antidote to the pharmakon, the multivalent drug, of global flows and circulations, which has proven so popular in the twenty-first century. Sadly, consumption of hydraulic metaphors continues to exert a soporific effect on scholars of the globalization of science. Scientific knowledge and practice, if they no longer 'diffuse' out from Europe, now seem to flow and circulate unimpeded around the world, as in some alluring imperial fantasy. The history of science once was proudly universal, latterly national and social, sometimes comparative across nation states, but now it is customary to explain the globalization of science, technology, and medicine as a process of laminar flow. Postcolonial approaches, though, can reveal the terrain that channels such circulation, showing the historical and political forms and interactions, the systematic exclusions and inclusions that make these flows turbulent. Globalization narratives tend to produce ornamental differences, whereas postcolonial framings show how we perceive and deal with radical otherness. For many decades, critical scholars in science studies have excelled in situating scientific and biomedical knowledge and practice, in putting them in their place – but how do we connect these multiple sites? The imperial gaze sees smooth, inescapable global flows; postcolonial critics instead see messy, uneven politics and diverse, contending agents amid the historical debris.

Postcolonial Genealogies and Antecedents

Postcolonial studies of science boast a complex genealogy, including relations with South Asian subaltern studies, indigenous knowledge traditions, feminist standpoint theory, colonial histories of science and medicine, and critiques of development. The connections with formal postcolonial theory are surprisingly sparse and feeble. While the cultural and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85057-6

textual analysis of Edward W. Said, Homi K. Bhabha, Gayatri Chakravorty Spivak, and others often has stimulated inquiry and suggested key terms, its abstract style and narrow literary scope restrict its appeal. Esoteric postcolonial theorists have found it hard to light out into new territories. In contrast, postcolonial scholars in science and technology studies, drawing on different sources, have favored richly textured historical and anthropological narratives – indeed, they are notably inclined to combine historical and anthropological approaches. Thus conventional criticisms (Thomas, 1994; Cooper, 2005) of the obscuring abstractions of postcolonial theorizing prove inapplicable and redundant in the case of densely empirical postcolonial studies of science.

Starting in the 1980s, South Asian scholars and activists have engaged in vigorous debate about the status and significance of European science, technology, and medicine, viewing the relations of imported practices with local knowledge traditions through Gandhian and postcolonial framings. Critics of European scientific dominance such as Ashis Nandy (1988, 1995) and Shiv Visvanathan (1997) have valorized Indian knowledge traditions and traced the diverse terrain of scientific practice. For Gyan Prakash (1999: 7), colonial science was 'a sign of Indian modernity,' translated and appropriated by Hindu nationalists to advance their causes. These critics of colonial and neo-colonial science and medicine render their topic of inquiry far more heterogeneous, hybrid, and contested than it seems in simple diffusionist accounts. Regardless of claims for the transcendence or universalism of science, in practice it appears to be doing specific political and cultural work on the ground. Importantly, postcolonial studies of South Asian science and medicine have expanded the range of what constitutes science and who is recognized as a scientist. Like their subaltern studies associates, critics of colonizing science reorient Antonio Gramsci, perceiving European dominance without hegemony.

In troubled, self-critical settler societies like Australia, New Zealand (Aotearoa), and Canada – and less so in more complacent ones like the United States – postcolonial scholars have focused on the interactions of scientists and indigenous people. With the Yolngu of eastern Arnhem Land, Australia, Helen Verran (1998: 238) has described "the politics waged over ontic/epistemic commitments," whether to science or traditional knowledge. Verran hopes for a community that "shares imaginaries and articulates those imaginaries as part of recognizing the myriad hybrid assemblages with which we constitute our worlds" (1998: 238). Like other postcolonial critics, she appreciates the messiness, contingency, and ineluctable heterogeneity of knowledge practices (Watson-Verran and Turnbull, 1995; Verran, 2002). Similarly, David Turnbull has studied the "interactive, contingent assemblage of space and knowledge" in diverse settings, arguing that "all knowledge traditions, including Western technoscience, can be compared as forms of local knowledge so that their differential power effects can be compared but without privileging any of them epistemologically" (Turnbull, 2000: 6; see also Chambers and Gillespie, 2000). Exploration of the contact zones between knowledge traditions has stimulated other efforts to multiply the sites of knowledge making and to destabilize geopolitical dominance. Such efforts include Linda Tuhiwai Smith's validation of indigenous research practices in *Decolonising Methodologies* (1999) and Raewyn Connell's (2007) affirmation of "Southern theory" in the social sciences.

Since the 1990s, philosopher Sandra Harding (1998: 305) has tried to 'locate modern sciences on the more accurate historical and geographical maps produced by the postcolonial accounts.' Relying more on feminist standpoint theory than on any particular postcolonial doctrine, Harding imagines a multicultural science that might one day encompass the knowledge and experience of women and the peoples of the Third World. She seeks to integrate indigenous science into Western 'ethnoscience' and build support for autochthonous Third World projects. Harding draws on historical studies of imperial science and medicine, anthropological descriptions of ethnoscience, criticism of development programs, and the scholarship and activism of South Asian intellectuals, such as Nandy, Susantha Goonatileke, and Vandana Shiva. Teetering on the edge of essentialism, she wants to take up the standpoints of non-European cultures in order to make a better future. She laments the "persistence of legacies of male supremacy and Eurocentrism in the work of even progressive science and technology scholars" (Harding, 2008: 214). But Harding's framing of Western and other sciences is surprisingly bipolar, with each pole representing an opposing standpoint, eschewing heterogeneity and hybridity (Harding, 2011). Indeed, it is hard to envisage the twain ever meeting.

The critical anthropology of 'development' is another rich source of postcolonial analysis of science, technology, and medicine. To some extent, such analysis responds to Paul Rabinow's call to "anthropologize the West" – to show "how exotic [the West's] constitution of reality has been; emphasize those domains most taken for granted as universal (this includes epistemology and economics); make them seem as historically peculiar as possible; show how their claims to truth are linked to social practices and have hence become effective forces in the world" (Rabinow, 1986: 241). In *Encountering Development*, Arturo Escobar (1995: 19) thus sought to investigate modernity "as a culturally and historically specific phenomenon." Akhil Gupta (1998: 20), similarly, in his study of agricultural development in India, has used a postcolonial framework to describe "hybrid discourses and practices and to delineate the intertwining of 'local' practices with global and national projects of development." Like other postcolonial scholars, Gupta wants to destabilize the "binaries of colonial and nationalist thought in pointing to the imbrication of the Indigenous in modernist discourse" (1998: 20). Other anthropologists of development and technoscientific modernity, such as Stacy Leigh Pigg (1997) and Chris J. Shepherd (2004), have helped to foster the postcolonial analysis of science and medicine.

The emergence of postcolonial studies of science and medicine is a particular manifestation of more general efforts, gaining force in the 1990s, to decolonize knowledge, to make visible subjugated practices and conjugated subjects. Thus Walter D. Mignolo has pushed for the destabilizing of Occidentalism through "border thinking," which implies the recognition and recuperation of the radical differences that global translations attempt to obliterate. For Mignolo (2000: x), "border thinking is more than a hybrid enunciation. It is a fractured enunciation in dialogic situations with the territorial

and hegemonic cosmology." Border thinking functions as a "machine for intellectual decolonization" (2000: 45). Similarly, Fernando Coronil (1996) urged us to move beyond Occidentalism in recreating our conjectures and methods. In this sense, our theories about the world are catching up with, or being co-opted by, the dispersive logic and multiple registers of contemporary globalization.

Postcolonial Actors and Scientific Travels

During the past 40 years, we have sought to situate science, technology, and medicine ever more securely and intricately in time and place. No longer transcendent or universal, science has come to appear as a series of complicated local accomplishments, the result of knotty social negotiations on site. While scientists may think globally, they act locally. But how do we connect the multitude of local case studies? "We need to understand," writes Steven Shapin (1998: 6–7), "not only how knowledge is made in specific places but also how transactions occur between places." Having put the view from nowhere in its place, how do we get from there to somewhere else? "If facts depend so much on … local features, how do they work elsewhere?" asks Simon Schaffer (1992: 23).

Actor-network theory (ANT) has provided one of the more appealing explanations of how science travels and becomes stable in various places. Originally, ANT was supposed to demonstrate how a series of translations through a network might keep science and technology invariant in different settings. The extension of networks could fix facts, rendering them as 'immutable mobiles.' Bruno Latour described how an object becomes robust and stable through developing better articulation with human and nonhuman actors. Society, nature, and geography therefore are the outcomes, not the causes, of these mobilizations, translations, and enrolments. Polarities of center and periphery, global and local, make little sense in these distributed networks. As Latour (1993: 117) insisted, "even a longer network remains local at all points." But the local in early ANT often was a very abstract place, a point where lines intersected, a location depleted of historical and social specificity. Shapin (1998: 7) went so far as to criticize the "militaristic and imperialistic language that is so characteristic of Latour's work." It seems that ANT initially resembled colonial discourse, not postcolonial critique. But later versions of the theory emphasized the modification and adaptation of objects and practices as they traveled – they suggested a less orderly topology of science. In a study of the Zimbabwean bush pump, Marianne De Laet and Annemarie Mol (2000) show how the object shifted shape and meaning from one village to the next, refiguring relations as it did so, all the while remaining identifiably a bush pump. De Laet and Mol recognize the displacement, transformation, and contestation that occur when science and medicine travel, the proliferation of hybridity and refashioning of identities and places that happen with contact. Even so, they continue to express reluctance to become too engaged with Africa, to take the postcolonial turn.

Recently, Latour has positioned ANT alongside postcolonial studies as ways of doing the anthropology of modernity. ANT, he argues, is a means of localizing the 'global,' of recognizing the connected locales where global scale making happens. Thus "globalization circulates along miniscule rails resulting in some glorified form of provincialism" (Latour, 2005: 190). Just as postcolonial historian Dipesh Chakrabarty (2000) urged us to provincialize Europe, Latour seeks to provincialize "global" science. Additionally, Latour (2005: 204) wants to 'redistribute' what counts as local: "no place dominates enough to be global and no place is self-contained enough to be local." We should concentrate on how forms of knowledge are translated from site to site, how practices, people, and things move around, adapt, become standardized, are seen as comparable and commensurable. Latour's postcolonial predicates become evident when we substitute 'empire' for his deconstructed 'society,' or for the 'global.' Postcolonial criticism and ANT both challenge claims of sovereignty, both situate scale making, and both shift focus from structures of dominance to patterns of interaction and connection. But Latour's absolute aversion to structure renders him unable to consider power and inequality – he resists the thought that some people and institutions have more power to shape interactions and make connections than others. He provides us with an implicitly postcolonial analysis, shorn of critique. While Latour complains that critical studies of science too often put the cart – filled with structures, contexts, and histories – before the horse, in his vision the cart disappears, leaving nothing but the unburdened horse.

Postcolonial Technoscience

In the late 1990s, a number of historians of science and medicine, stimulated by new critical and heterogeneous imperial histories, came to embrace a postcolonial thought style, not only in their historical analysis, but also in explaining the dispositions of our contemporary science, technology, and medicine (Anderson, 1998, 2004). In effect, this meant thinking more anthropologically, working athwart conventional European trajectories. These postcolonial scholars regularly issued manifestos and other programmatic statements. They arranged workshops and special symposia within meetings of organizations like the Society for Social Studies of Science and the American Anthropological Association. When introducing a postcolonial thought style to science studies, they also were seeking to expand the scope of postcolonial studies, to add science and medicine to its usual literary repertoire.

In 2002, Gabrielle Hecht and I edited a special double issue of *Social Studies of Science* (32: 5–6), with the ambiguous title, "Postcolonial Technoscience." In the introduction, I wrote:

> A postcolonial perspective suggests fresh ways to study the changing political economies of capitalism and science, the mutual reorganization of the global and the local, the increasing transnational traffic of people, practices, technologies, and contemporary contests over 'intellectual property' … We hope that a closer engagement of science studies with postcolonial studies will allow us to question technoscience differently, find more heterogeneous sources, and reveal more fully the patterns of local transactions that give rise to global, or universalist, claims.
>
> (Anderson, 2002: 643)

The assembled articles, which addressed African nuclearity, Aboriginal fire regimes, Guiana space research, and American biosecurity fears, advanced our knowledge of "the localness of technoscientific networks, the situated production of 'globality', the transnational process of displacement and reconfiguration, the fragmentation and hybridity of technoscience" (Anderson, 2002: 651). Before long, the journal *Science and Culture* (14: 2, 2005) also offered a special issue on postcolonial studies of science (see the introduction by McNeill, 2005).

Some scholars suspected the politics of this enterprise, fearing that it might be harnessed to emerging nativist and nationalist knowledge claims. Itty Abraham, for example, supported postcolonial approaches that aim to "understand both the situatedness of local knowledge practices [and] their movement through space" (Abraham, 2006: 210). But he was concerned when the postcolonial was identified as a "site for understanding the clash of knowledges and the formation of alternative modernities." The rise of Hindu nationalism made him worried that "when the postcolonial is linked to a fixed site of irreducible knowledge claims, it articulates an ontology that ties knowledge to a location as a singular and essential quality of space" (Abraham, 2006: 210). Postcolonial scholars might end up as fellow travelers with the nationalists who assert their own special modernity. Abraham's warnings perhaps were most pertinent to those postcolonial theorists who tend to essentialize ethnosciences or discern place-specific 'standpoints.' Even so, scholars like Helen Verran, in her engagement with the Yolngu people in Australia, may argue that essentialized Indigenous knowledge performs a different politics in the settler society, where it operates as a decolonizing strategy, not a nationalist one. Although South Asia has been the modal site for postcolonial thinking, there may be times when we need to provincialize India in the postcolonial analysis of other sites.

When Vincanne Adams and I next surveyed postcolonial studies of science, we chose, somewhat quixotically, to make particular recourse to Said's 'traveling theory,' his advocacy of a critical spatial consciousness, recognizing the territorial entanglements of Western cultural forms with others. As the imperial project is taken apart, or heard as contrapuntal, "its incorporative, universalizing, and totalizing codes [are] rendered ineffective and inapplicable" (Said, 1983: 29). Adams and I believed:

> This requires a multiplication of the sites of technoscience, revealing and acknowledging hidden geographical notations and power relations, and further study of the mechanisms and forms of travel between sites. It means we have to be sensitive to dislocation, transformation, and resistance; to the proliferation of partially purified and hybrid forms and identities; to the contestation and negotiation of boundaries; and to recognizing that practices of science are always multi-sited.
>
> (Anderson and Adams, 2008: 183–184)

Although by this stage such statements may have become redundant, we went on to claim that postcolonial analysis offers a "flexible and contingent framework for understanding contact zones of all sorts, for tracking messy translations and transactions that take place between different cultures and social positions, including between different laboratories and disciplines even within Western Europe and North America" (Anderson and Adams, 2008: 184). That is, the postcolonial is not limited to former empires, but is available as a means of deconstructing any claims to sovereignty, including the scientific and medical ones asserted along North Atlantic shores. Peter Galison provides a vivid example of this methodological amplitude when he draws on postcolonial Pacific anthropology to describe the 'wordless pidgins' and 'wordless creoles' that allow communication between theorists, experimentalists, and instrumentalists in the 'trading zones' of Big Science in the United States – an analogy that recasts the epistemic privilege often assigned to theory in physics (Galison, 1997: 463–464).

Aside from various manifestos, and often indifferent to them, good work in postcolonial studies of science and medicine has proceeded apace. In view of the profusion of postcolonial inquiries, it is perhaps invidious, though necessary, to select a few recent examples. In *Being Nuclear*, Hecht (2012) displaces the standard geopolitics of things 'nuclear,' making Africa central to this science and industry, and thereby reshaping the 'global' nuclear order (see also Hecht, 2002, 2011). Claire Wendland (2010, 2012) examines medical training in Malawi, recasting Africa as a site of knowledge making and intellectual hybridity, not just of lack and inadequacy. In a provocative study, Johanna Crane (2013) shows how African suffering and structural inequalities permit the development of 'global health' research and other neo-colonial biomedical projects, which marginalize and discount local expertise. Gabriela Soto Laveaga (2009) puts Mexican campesiños, formerly invisible to historians, into the story of the development of the contraceptive pill, taking seriously their own scientific claims, and tracing how involvement in science changed their sense of themselves and their place in the world. In a series of articles, Amit Prasad (2005, 2006) maps the postcolonial trajectories of magnetic resonance imaging technology in India and the United States, revealing transnational shape shifting, the concatenation of epistemes and methods, in modern technoscience (see also Prasad, 2008). My own book on the transnational investigation of the brain disease kuru, *The Collectors of Lost Souls* (Anderson, 2008), also exemplifies the postcolonial study of technoscience. Applying insights from Melanesian anthropology to explain the complex exchange relations between scientists, local people, and other scientists, *Lost Souls* traces modern kula rings and other long-distance trade partnerships, casts scientists as sorcerers, and lets isolated 'primitives' speak as cosmopolitan figures. In it, I treat "ostensibly global science as though it were assembled out of a set of rather peculiar local achievements" (Anderson, 2008: 7). Such studies – a small sample of those available – are among the salients in the field, holding out against the sovereign 'global flows,' which prove so alluring yet so facile.

Conclusion

Postcolonial approaches in science studies allow for a recognition of the patchy decolonizing of scientific production and medical practice, a process occurring gradually for more than 100 years, and greatly amplified in the past 20 years. This style of analysis takes on the heterogeneity and hybridity

that finds expression in any contact zone, but it does so aware of the persistent or recursive colonial inequalities and exclusions that shape these situated interactions. Postcolonial scholars and activists seek to render more turbulent the supposedly laminar global flows, to deconstruct and impede grandiose claims to sovereignty and hegemony. Therefore they examine critically the multiple local sites where scale making and translation take place in science, and trace the connections and the ruptures between such places, across a rugged terrain.

And yet, it could be said that the imperatives and methods of science studies themselves have remained almost untouched by postcolonial critique. Escobar argues that the postcolonial 'crisis' in our representation of modernity calls for "new theories and research strategies; the crisis is a real conjunctural moment in the reconstruction of the connection between truth and reality, between words and things, one that demands new practices of seeing, knowing, and being" (Escobar, 1995: 223). Can science studies participate in postcolonial analysis without changing its methods? Is it business as usual over a bigger geographical range and with a larger cast of actors? In becoming postcolonial, how might science studies be transformed? What, for example, would making "Asia as method" (Anderson, 2012) entail for the sort of questions we ask of science, medicine, and technology – and for how we might answer them? Conventional historical and anthropological studies probably are inadequate for the task. We are waiting for the new generation of scholars and activists, who will show us what the postcolonial studies of science might become.

Abstract

Postcoloniality is the unprecedented, complex predicament faced by individuals, societies, and governments after European colonial rule. This article addresses elements of postcolonial predicament including prospects for agency among dominated 'subaltern' groups, teh power of the West, liberation in theory and reality, and the relation of postcoloniality and globalization. Differences between diverse eighteenth-century and twentieth-century decolonizations lead to contrasting postcolonial ideologies: while theorists have recently sought ways to make 'postcolonialism' a viable political perspective for excolonies, in a different way, US ideology and power also manifest a postcolonial political will in globalization.

Postcoloniality is the unprecedented, complex predicament faced by individuals, societies, and their governments after the end of European colonial rule. An increasing number of social scientists, especially in the 1980s and 1990s, have found conceptions of postcoloniality useful for characterizing many contemporary societies. Theories of postcoloniality have emerged especially as more established alternatives – theories of modernization, of underdevelopment, of the Third World, and of revolution – have lost their power to explain the present and predict or guide the future. The premise of most postcoloniality theories is that 'The history of the West and the history of the non-West are by now irrevocably different and irrevocably shared' (Sangari, 1995, p. 147).

Writings on postcoloniality range widely in discipline and scholarly methods, and might be typifiable first of all by an attitude, even a mood: disillusionment coupled with commitment, disillusionment with the conspicuous failure of decolonization to produce a world of peace, prosperity, and real liberation, coupled with commitment to diagnose that failure and seek improvements or alternatives. In a British colonial prison during World War II, Jawaharlal Nehru wrote that 'Out of this crucible of war, wherein so much is melting, we hope that something finer will emerge for the West as well as the East, something that will retain all the great achievements of humanity and add to them what they lacked' (Nehru, 1982 [1946], p. 81). Thirty-seven years later, as he helped launch the 'Subaltern Studies' school of history, Ranajit Guha declared the 'historic failure of the nation to come to its own' in postcolonial India, its failure as either a bourgeois democracy on the European model or a socialist 'new democracy.' He declared the study of this failure 'the central problematic' for the historiography of India (Guha, 1982, p. 7). Similarly, Frantz Fanon wrote in the late 1950s, in the midst of the Algerian anticolonial war, that 'Decolonization is the veritable creation of new men,' that 'the European game has finally ended; we must find something different,' and that 'It is a question of the Third World starting a new history of Man' (Fanon, 1968, pp. 36, 312, 315). Thirty-five years later, in the Afterword added to his classic philological study *Orientalism*, Edward Said specifically abjured the idea of 'fixed identities battling across a permanent divide' of Europeans and others (Said, 1994, p. 335), in favor of more nuanced multicultural critique of power. While some theorists voice a continuing optimism that, especially in Southern Africa, Eastern Europe, and Southeast Asia, the end of the twentieth century has inaugurated a new age of revolutions (e.g., Comaroff, 1996), the dominant tendency in most studies of postcoloniality is critical dissection of utopian anticipations.

To date, discussion of postcoloniality has been more extensive in the Humanities than in the Social Sciences. Critical, often reflexive, theorizing about postcolonial identity and experience has been more extensive than social scientific research into political, economic, and cultural dynamics of postcoloniality. However, controversies in postcolonial theory have provoked fruitful research in anthropology, history, geography, sociology, political science, and other social sciences, characteristically entailing profound political as well as analytic questions. Good available readers on postcolonial studies include Williams and Chrisman (1994) and Ashcroft et al. (1995). This article centers on efforts to address three powerful antinomies in postcolonial theory, concerning (a) the agency of dominated groups, whether they determine their own fate, (b) the power of the West, whether Western paradigms are inevitable, and (c) the goal of liberation, and when and how postcoloniality might ever end. The article concludes with the tensions between postcoloniality theory and postmodernism, and with efforts to relate postcoloniality and globalization, arguing against portrayals of globalization as the end of postcoloniality, in favor of depiction of the two as intrinsically related.

Can the Subaltern Speak?

In 1988, literary critic Gayatri Spivak posed the above question as a challenge to the 'Subaltern Studies' school of historians (Spivak, 1988). The Subalternists, following Gramsci's theory of class politics in culture, have sought to uncover hidden realities of dominated people's experience and agency in South Asia. The 'Subaltern Studies' project, and Spivak's question, have led to debates and research globally on class, status, culture, and power especially in colonial and postcolonial societies.

The premises of the Subalternists have been, first, that prior histories of colonialism, decolonization, and the postcolonial nation-state have focused on elites, and second, that especially under colonial conditions, elite culture has not been hegemonic, i.e., has not established rituals and routines for social order unchallenged by 'subalterns' or lower class and status, dominated people. In order to explain why a unified postcolonial nation has failed to take shape, Subalternists seek to understand the social experience, collectivities and initiatives of 'subaltern' groups. The original South Asian 'Subaltern Studies' of peasant insurgencies and labor struggles have joined a much broader stream of scholarship on colonial and postcolonial politics, broader not only geographically but also topically, including especially in the 1990s many studies of sex and gender relations, institutions, and imaginaries. However, the issue of the failure of decolonization and the postcolonial nation-states remains central. Efforts have begun to identify positive, existing alternatives to 'the nation' as a form of social organization, not only in South Asia but also in East Asia (notably Duara, 1995), the Americas and elsewhere, and also to understand the social legacies of specifically colonial and postcolonial state structures (e.g., in Africa (Mamdani, 1996), in Indonesia (Pemberton, 1994), and in India (Pandey, 1990)).

In the context of research seeking to isolate colonial pathologies and celebrate successful resistances to them, Spivak's question attracted enormous attention because it challenged a second tier of scholarly premises. Phrased with a literary critic's focus on voice, 'Can the Subaltern speak?' quickly metamorphosed into a question about coherent, autonomous agency, and initiative. Is it possible for 'subaltern' people to shape their own society and culture? Precisely as a radical among philologists, Spivak had insisted that representation in a literary or semiotic sense must be reconsidered in connection with representation in politics, representation in the sense of any capacity for a person to be the agent of, to stand for, the will of other people. Do subalterns have any real power to represent themselves, or is that precisely the lack that constitutes them as subaltern?.

Social scientists have come to recognize empirical as well as theoretical issues here. In research on postcolonial societies, the question of subaltern political agency has intersected with studies of class and ethnic structure of anticolonial movements and postcolonial governments, and with studies of democracy in postcolonial conditions. While one tendency in contemporary scholarship is to discover unnoticed ways and means by which subaltern groups preserve themselves, maintain autonomous self-control, and even augment their life chances (e.g., Scott, 1985), another trend is to seek aspects of political structure, global and local, that might account for the reproduction of extremities of domination and violence in postcolonial societies (e.g., Tambiah, 1996), and a third trend is to seek to reintegrate the questions about colonial and postcolonial subalterns with studies of domination in metropolitan societies (e.g., Stoler and Cooper, 1997). Are postcolonial governments especially likely to be bound to the interests of urban, elite, and ethnically marked subpopulations? Are 'subaltern groups' in such societies less likely to exercise routine rights as citizens, and more likely to sustain whole institutional apparatuses of avoidance and resistance, 'informal' economies, even labor migrations kept deliberately invisible to the postcolonial state? No consensus has emerged. However, it does grow increasingly clear at least that, systematically, the nation-state does not 'come into its own' in postcolonial societies, and 'subaltern' classes in them are neither powerless nor as powerful as citizens in the West.

Provincializing Europe

Is the postcolonial world destined (or doomed) to follow the West's lead? To fit Western molds? Is the history of the West the central axis of world history? If it isn't, then how can sense be made of colonial history? Research assessing the successes and failures of postcolonial societies that sought alternatively to emulate and to refuse Western models (China, Singapore, Japan, Malaysia, Indonesia, India, and many sites in Africa), especially concerning successes of non-Western capitalisms, and the failures of self-proclaimed socialist revolutions, suggest that efforts to understand the West either as 'exceptional,' successful for particular cultural or material reasons, or as 'universal,' a distillation of necessities, both fail to grasp the more complex dynamics of the actual history of capitalism, colonialism, and the rise of the nation-state. Anticipations kindred to those of Fanon and Nehru, hoping more or less radically for a new order to supplant the civilization of Europe, were common among anticolonial intellectuals of the mid-twentieth century. These anticipations frequently entwined in a variety of ways with socialist and communist projects for social reconstruction and/or revolution, an end to a capitalist era. For this and other reasons, decolonization became deeply enmeshed in the narrow frame of the Cold War, and was dramatically reconceived within it. The question of the future relation of excolonies and excolonizers became, temporarily, reduced to matters of allegiance in a grand global dualism. Social scientists operated under the premise that all 'Third World' new nations were destined as they 'modernized' to join either the 'free' or 'Communist' worlds (see Pletsch, 1981). However, by the end of the century much that was taken for granted in this Cold War common sense was in doubt, was under scrutiny, or was repudiated outright, not only concerning the viability of a revolution against capitalism but also concerning modernization and the nation-state.

In the late-twentieth century, great popularity accrued among scholars for Benedict Anderson's vaguely Marxist theory that the nation as an 'imagined community' was central to the century's global culture (Anderson, 1983), but at the same time, disquiet about actual postcolonial nations and states led to new critical questions. Partha Chatterjee mounted the most influential challenge to the premise of the nation-state for excolonies. Chatterjee amplified and reconsidered the implications of parts of Anderson's argument, that 'the nation' was a form for politics linked intrinsically to Enlightenment social theories, a political format pioneered in the Americas and Europe, and then 'pirated' in already 'modular' format as colonies were refashioned and new nations built. Insofar as this is what happened, then, decolonization was not actually a break from Western hegemony. 'Europe and the Americas, the only true subjects of history, have thought out on our behalf not only the script of colonial enlightenment and exploitation,

but also that of our anticolonial resistance and postcolonial misery' (Chatterjee, 1993, p. 5). Chatterjee doubts that 'our imaginations must remain forever colonized' (Chatterjee, 1993, p. 5). However, the question of how to decolonize political imagination, and whether or where it has already been decolonized, has been a provocative one for postcolonial studies. While another influential critic has argued that postcolonial critique of Western universalisms has opened a 'third space' outside both local, cultural particularisms, and modernist universalism (Bhabha, 1994, pp. 36–9), others have defined postcolonialism instead as the dream that this could be done, 'the need, in nations or groups which have been victims of imperialism, to achieve an identity uncontaminated by universalist or Eurocentric concepts and images' (During, 1987, p. 3), or the quest for a new relationship with 'the intimate enemy' (Nandy, 1983). In this sense, as Lenin once hoped that a United Front politics in colonies could use bourgeois nationalism as a stepping stone to a proletarian revolution, a postcolonial perspective is proffered by some as the key to a new political future. With or without such a dream, the matter remains of how to understand the impact of 'the West' and its (possibly parochial) universals on one-time colonies in both the past and the present. Touchstones for controversy have included 'world system' models of a globally coercive Western-centered economy, and models of globally hegemonic Western culture. World system economic models have largely been encompassed by approaches emphasizing the irreducibility of both global and local economic forces, and the necessity to understand both. While support increases for models of economic 'globalization' that see global economic forces and relations increasing in their influence over time, the causes of the rise of the West as the pre-eminent capitalist center, and the place of colonialism in that history, are still much debated. Similar controversies have followed models of globally hegemonic Western culture, notably Edward Said's landmark study of the kind of discourse he named 'Orientalism,' discourse that constitutes the East and West comparatively, the East as the inferior antithetical other. Said's study has been criticized, ironically, for itself overriding the possibility of non-Western political discourses, for itself undermining the possibility of a world history centered anywhere but the West. Studies have also begun of processes of cultural globalization and of the crucial process of the localizing intermixture of global and local cultural elements that clearly accompanies the development of global cultural connections, the process Hannerz has named 'creolization' (Hannerz, 1992).

At their extremes, globalization models can be as simple in their symmetries as conceptions of postcoloniality can be stark in their asymmetries. Recharacterizations of global culture in terms of flows, links, and hybridities, and inquiry into 'modernity at large' (Appadurai, 1996), have added an important complexity to studies of postcoloniality, undermining the starkness and simplicity of the colonizer–colonized dualism, and challenging the premise of continuing cultural superiority of the West. However, the situation of postcoloniality requires attention to asymmetries. Reconsidering the past, present, and future place of the West, postcolonial theorists have grown as skeptical of triumphalist visions of reversal, of a non-Western overcoming of Western culture, as they are critical of intrinsically colonial visions of Western superiority over the rest. In *Provincializing Europe*, Dipesh Chakrabarty suggests a way out of the antinomies generated by efforts to reckon with Western domination (Chakrabarty, 2000). The paradox in all postcolonialisms that seek a triumphant postcolonial succession to Europe at history's center, Chakrabarty shows, is that even in such a success, the historical structure would still be 'First in Europe, and then elsewhere.' Europe indeed pioneered the form of historicist explanation that gives time a single processural center, giving capital and its culture of Enlightenment a unified place, time, and pattern of development in Europe, while occluding all inassimilable complexities of its earlier and later history elsewhere. However, Chakrabarty argues for abandoning such historicism, in favor of a method which never confines universal history, and provincializes Europe not from a new center, but instead by understanding Western cultural history, also, as one of creolizations (to use Hannerz's term here). Following Chakrabarty (or the similar, 'anti-Hegelian,' argument of Duara (1995)), one can provincialize Europe, confront and unmake colonial asymmetries, without a triumphalism that will inevitably, fatally, unmask as mimicry of European colonialism's own naive historicist egocentrism. Reflection on how, in recent but past centuries, Europe encountered and came in particular, powerful, but not all-powerful, ways to embody and develop universals of capital, democracy, science, etc., might point toward alternative developments in the past and the present, and possibilities not yet recognized for the future, rather than renewing an imperative to overcome empires already dead. In any case, postcolonial theorists have grown weary of battle with colonial ghosts.

When, and How, Can Postcoloniality End?

It will now be useful, and easy, to clarify the distinction between postcolonialism and postcoloniality. If postcolonialism is the aspiration for a profound political perspective to emerge from the experience of decolonization, postcoloniality is the unprecedented political predicament that decolonization has delivered many societies. The antinomies that fuel the struggle to constitute a postcolonialist political vision are, in less ideological form, equally inescapable for those without postcolonialist aspirations. Postcolonialist quests for political mission via subaltern standpoints struggle over what to expect from and for subaltern political agency. However, vast, dominated, and politically active populations no doubt exist in subaltern positions in postcolonial societies. Any coherent postcolonialism would seem to require a history both centered on and decentering of Europe, but, no doubt, Europe did once dominate, in various and varying ways, the societies it colonized. The question of how, and whether, that domination can be (or has been) ended is crucial to the third antinomy for postcolonialism, the third aspect of predicament in postcoloniality.

Anticolonial theorist and activist Franz Fanon insisted on the goal of liberation, not mere decolonization, for European colonies. Decolonization was something done for, and to, one-time colonies, where the goal should be actual liberation. In fact, as Fanon perceived, in the aftermath of World War II, the European empires disintegrated with extraordinary rapidity, and

(except for the French and Portuguese) with little violence: Fanon perceived why. In the atmosphere of the Cold War, Western powers and especially the newly pre-eminent United States greatly feared radical new states emerging from wars of liberation, and preferred to shape successor regimes and constitutions through a pre-emptive orderly process. As Fanon put it, the message flashing was 'for God's sake let's decolonize quick,' as the pieces of European empires were reconfigured into the nation-state form of 'self-determination' required by the new, US-fashioned United Nations (Fanon, 1968, pp. 70, 79).

By many diagnoses, decolonization and not genuine liberation was what the new 'Third World' received. But the problem of what would constitute genuine liberation, and which groups merit it, has become increasingly complex. As Firth (2000) has demonstrated, rhetorics of decolonization and liberation have expanded and proliferated after the breakup of most of the European empires has already been accomplished, expanding to articulate aspirations both of groups within nation–states (Biafrans in Nigeria, Kurds in Iraq) and new kinds of groups (women, indigenous peoples, even environments). If the premise of the United Nations has been that the nation-state as a political form constitutes the ultimate form of self-determination for all peoples, that simple, symmetric premise has been called into question. While most reckonings of postcoloniality focus upon the need to overcome asymmetries past, another approach entirely is to reckon it the onset, rather than the aftermath, of something, the predicament constituted for capital-poor excolonies by their re-establishment within the formal symmetries, and limited liabilities, of the United Nations model (Kelly and Kaplan, 2000). From this perspective, the goal of liberation itself has become a very specific trap, as formally independent and autonomous political standing comes systematically to entail perpetual clientage, expanding debts and ongoing substantive subservience to outside agencies and agendas. Like the 'free laborer' perceptively critiqued by Marx as free of all access to means of production, these liberated states are, by their very freedom and formal equality, radically limiting of the life chances of their citizens, especially their subalterns. In an interesting recent controversy, Tambiah (1996) rejects the arguments of Pandey (1990) explaining postcolonial communalist violence in South Asia as a legacy of colonial policies that emphasized and institutionalized communal political differences. Tambiah argues that endemic political violence is a phenomenon of democracy especially in postcolonial conditions, conditions that engender a spiral of destructive, effervescent leveling crowds. The crowds seek not liberation but leveling, destruction of privileges perceived as unmerited, especially across ethnic lines.

Boundary issues have arisen concerning which societies are postcolonial, especially concerning East Asian societies never formally colonized, and the Americas where the legacy of earlier, Iberian domination and earlier independence movements must be calibrated with the history of European colonies in Africa, Asia, and elsewhere. Sociologist Haejoang Cho has argued forcefully that Korea and other East Asian societies were colonized by the West, with becoming colonized defined as coming to require foreign means, methods, and tools simply to live and to think (Cho, 1992–94). For the Americas, Klor de Alva (1992) has argued that few or none of the societies outside the Caribbean are postcolonial in fact, that regardless of mestizaje ideologies, Latin American societies are descended not from colonized peoples but largely from the colonizers. As with most of Latin America, whether the United States is postcolonial depends upon the definition adopted. The question is most interesting when connected to different boundary issues concerning postcoloniality: its relations with postmodernism, and with globalization.

Is the post- in postcolonial the post- in postmodern? (So asked another literary critic, Appiah (1992).) Can either end? Dramatic, relativistic postmodernist proclamations that the Enlightenment universals are dead have been countered, Appiah argued, by the fact of misery in postcolonial societies, leading postcolonial political movements to ground their calls for new reforms in ethical universals. While postmodernism offered a first alternative vision to the stalled modernization logic of the Cold War, at present conceptions of both postcoloniality and globalization offer more dynamic alternative formulations. How, then, are postcoloniality and globalization connected? Some scholars envision globalization as the successor, the late capitalist liberator from postcoloniality, as the globe moves from Western modernity to modernity at large or to alternative modernities, negating all vestiges of asymmetric colonial relations. The counter argument (Kelly, 1998) is that postcoloniality and globalization are two sides of the same coin, the coin of American power, phenomena not necessarily of a 'late' capitalism but certainly of the new form capitalism has taken under US leadership in the twentieth century. If this is the case, if decolonization and globalization are the fruit of US-led quests for political self-determination and economic open doors, then Europe has already been provincialized by an explicitly anti-imperial agenda, and the predicaments of postcoloniality are the consequences, precisely, of a postcolonialism already instituted. David Scott has perceptively observed, in the first book with 'After Postcoloniality' in its title, that in the late twentieth century, in the wake of the global resurgence of liberal democracy and the failures of socialist states both Soviet and non-aligned, 'it is no longer so clear what "overcoming" Western power actually means' (Scott, 1999, p. 14). Perhaps, then, the time has come for dividing 'the West' into its colonial European and twentieth-century American versions. In that case, postcoloniality could end only when American power is as thoroughly confronted as European power has been, and the limitations intrinsic to the formal symmetries of the political present are as fully overcome as have been the formal asymmetries of the colonial past.

Postindustrial Societies

Abstract

The term postindustrial society presupposes categorizing society based on an economic means of classification. Its use rests on assessing the relative status of manufacturing industry as an economic sector. Significant adjustment in sectoral location and nature of employment precipitated by late-twentieth-century deindustrialization in the developed world led many social theorists and critics to predict broad changes throughout domains of everyday life. Some began to speak not only of sectoral transformation but also of an emergent 'postindustrial society.' Following earlier agrarian and industrial 'revolutions,' postindustrialism suggested yet another revolution that would again transform how societies were organized.

General Introduction

To employ the term 'postindustrial' to society is to seek a manner of categorizing society largely dependent on an economic means of classification – or, at least, one using an economic point of reference. Specifically, of central concern is the relative status of manufacturing industry as a delineated sector in an overall economy. As the importance of this sector declines in a particular country as measured by its contribution to job creation and that society's gross domestic product – the market value of formally recognized goods and services produced in a given period of time – many social observers have chosen to describe such societies as postindustrial in order to emphasize displacement of the industrial sector.

In the late nineteenth century, Western countries shifted from economies largely dependent on agricultural production to one focused on industrial production of goods. This was a shift that led legions of workers to abandon farming and rural areas for higher wages in growing urban centers of manufacturing. For much of the twentieth century, countries that had led the Industrial Revolution – including England and the United States – experienced robust growth in industrial as well as service sectors. Beginning in the 1970s, however, it was evident that the industrial, or secondary, sector was joining the primary sector, defined by agriculture, in decline as practically all net employment growth could now be measured in an ascendant service sector – generally referred to as the tertiary.

This kind of broad economic change may be referred to as 'sectoral transformation' of the labor force. Importantly, while characterization of a society through reference to the relative importance of an economic sector might suggest a limiting perspective, exploring implications of a possible shift to a postindustrial economy has incorporated a broad range of subjects that will be at least partly addressed in this article. In the developed world, such a significant alteration in the sectoral location and nature of employment led many to predict far-reaching social changes throughout varied domains of everyday life. Some social theorists began to speak not only of sectoral transformation but also arrival of a 'postindustrial society.' That is, following both the agrarian and industrial revolutions, postindustrialism suggested yet another revolution that would again transform the way that a society itself was organized.

Historical Context for Development of Term

Although used as early as the second decade of the twentieth century, it was not until the years following World War II that the term postindustrial was again applied in discussions of social development. In his *The Age of Extremes: A History of the World, 1914–1991*, the historian and social theorist Eric Hobsbawm (1994) asserted that even while many societies had been profoundly transformed through this war, it was difficult to characterize a world of seeming constant change. In the period following the global watershed that this military conflagration represents, a variety of historians and social scientists sought to describe an emerging age and to confer an all-encompassing identity that sensibly pulled together disparate changes that were occurring since the war's end. Most attempts appended the prefix 'post' to one or another core concept used in characterizing the preceding, prewar era. Accordingly, scholars have offered such suggestive combinations as 'postcolonial,' 'post-Fordist,' 'postmodern,' and, of course, 'postindustrial.'

The latter two terms are clearly related in the attempts of those using them to make sense of significant changes taking place during the second half of the twentieth century. The term 'postmodern' has come to designate a period thought to have begun in the 1960s and generally thought to be defined by a decentered array of cultural paradigms coexisting without any one being dominant and that is economically determined by the particular qualities of a form of capitalism distinct from the prewar era. The economist Amitai Etzioni (1968) applied the term postmodern to mark the end of the modern period by virtue of sweeping changes after the war in the quality of communications, knowledge production, and energy. For the philosopher and literary theorist Jean-François Lyotard, knowledge in the postmodern is produced through questioning existing models, inventing novel ones, and rejecting the 'grand' or 'meta' narratives that he considered defining features of modernity. Such narratives would include expressions of modernist faith in progress – as achieved through science and technology – as the driving force behind history. Explicitly linking a postmodern period with emergent postindustrial society, Lyotard (1984: p. 3) writes that "Our working hypothesis is that the status of knowledge is altered as societies enter what is known as the

postindustrial age and culture enters what is known as the postmodern age." For Lyotard, social organization in the postindustrial society is built on rapidly expanding scientific knowledge, computer-processed information, and advanced technology while postmodern culture, at the same time, encourages deconstruction of master narratives and rejection of totalizing theory.

Not unlike social theorists a century earlier – such as Henri de Saint-Simon, Karl Marx, and Fredrich Engles – who tried not only to make sense of but also shape developments that they observed, there is a prescriptive element to the pronouncements of many late-twentieth-century social theorists. That is, one can see a degree of reflexivity that suggests an attempt to shape the direction of public policy, or at least the character of scholarly or public debate, through the basic quality of their analyses and accompanying assertions.

Orienting Theoretical Developments

In his *Old Worlds for New: A Study of the Post-Industrial State*, a collection of previously published essays, architect and social critic Arthur Penty (1917) called for abolition of industrial practices, development of what he referred to as the 'postindustrial state,' and a corresponding rise of decentralized, artisanal workshops. Ultimately, it was Penty's desire that – through these workshops – social spheres of work, leisure, and family could be brought together after having been functionally separated during the Industrial Revolution. For Penty, an avowed antimodernist, World War I marked the end of an era and time for fundamentally rethinking the nature of society. Further organization of industry through principles of 'scientific management,' those that characterized the prescriptions of the influential mechanical engineer Frederick Taylor, promised a decreased demand for labor that would exacerbate conditions that had just led to worldwide conflict.

Frederick Taylor's (1911) concepts and practices – such as those captured in his most cited text *The Principles of Scientific Management* – not only represented the beginning of a managerial era in industrial production but also hastened the craft era's end in the United States. Taylor's work highlights a burgeoning relationship between rationalization in general and labor control methods in particular. Although Taylor's principles were specifically intended to address perceived problems of labor while increasing production efficiencies in the workplace, effects of his scientific management spread widely from the factory floor to shape practices basic to the conduct of everyday life. This was a process facilitated, at least in part, by the influence of economist John Maynard Keynes whose theories provided a ready vehicle through which 'Fordist' ideals of consumption and the promotion of consumerism – a necessary complement to mass production – could be elevated, with the help of state agencies, to the status of primary engine for economic growth.

Henry Ford is widely credited with employing 'assembly lines' in his automobile factories as a means of streamlining routinized mass production of a standardized product. Embracing Taylor's principles, Ford maximized efficient use of inputs – both material and human capital – in order to maximize corporate profit. Born of his marked achievement putting scientific management to work on the assembly line, 'Fordism' has been used to describe not only what was increasingly practiced in the industrial sector during the twentieth century but also the ways of work generally and even the basic form of a society wrought by the imperatives of standardization and mechanization. Widespread application in the twentieth century of both Taylorist and Fordist principles of work rationalization led to what some have decried as a kind of degradation of work.

By the late 1960s, Fordism began to break down as America's industrial production began its steep decline. With arrival of the 1980s, the basic Fordist cycle of increasing wages coupled with rising production and consumer demand could no longer be sustained. Inflexible bureaucratic business organization and the work practices associated with them appeared too slow to respond to changing consumer demands. It was at this time that the term 'downsizing' entered the American vernacular as a means to describe the way in which a variety of companies sought to cut costs by employing fewer workers even while they sought to maintain or increase overall productivity.

An American sociologist drawing almost exclusively on evidence from the United States, Daniel Bell (1973) attempted to provide an explanation – with publication of his book *The Coming of Post-Industrial Society* – for emerging economic, social, and cultural conditions in developed countries during inchoate industrial restructuring. Increased efficiency in the industrial sector, first stimulated through scientific management and later achieved through technologically fueled automation, had led to sharp declines in manufacturing jobs. Bell asserted that changes taking place as a result of this shake-up constituted not merely a shift from an economy based on the production of goods to one based on the production of knowledge, but a fundamental change in the nature of knowledge itself. Specifically, this transformation would be accompanied by increasing importance of scientific rationality expressed in economic, political, and social spheres.

This change in the production and quality of knowledge would be aided by technological advances such as powerful computers that could automate data collection and manipulation and thus place increased value on analytical, higher order knowledge skills. Daniel Bell's (1960) work on postindustrial society built on his earlier book *The End of Ideology* in which he argued – with modernist optimism – that ideologically driven politics would give way to a more deliberate, conscious guidance of the economic sphere through expert application of scientific and theoretical knowledge. While *Coming of Post-Industrial Society* may be seen as a rethinking of his previous position that technocratic doctrine would bring a socially engineered peace facilitated by informed experts seeing to a rational distribution of wealth, Bell held that this emergent postindustrial society was one in which a free-market system alone cannot be left to set social priorities.

While Bell identified most of the transformations that he envisioned for a postindustrial society as broadly beneficial, in Daniel Bell's (1976) book *The Cultural Contradictions of Capitalism* he nevertheless identified a growing disconnect between social structure and culture wherein many people would find themselves with less clearly defined roles than in

earlier times. In the postwar period, service sector jobs expanded rapidly leading to changes in both the character and social significance of employment. Developed nations like the United States were beginning to contend with emergent issues born of what many began to refer to as 'mass' society – including mass consumption and, specifically, mass culture. Writing a book that would help define a genre of sociological and other inquiries, law professor and later sociologist David Riesman's (1958) book *The Lonely Crowd* claimed that in those countries that had entered a stage of mass culture, individuals were increasingly guided or 'directed' by norms and values conveyed to them by mass media – enabled by technological advances in communication – as well as by peer groups defined, at least in part, through shared engagement in particular leisure activities.

In this way, Riesman felt that a defining, even 'revolutionary,' characteristic of postindustrial society would be a shift from an 'inner-directed' social character derived from norms and values of the family and, to a lesser extent, community, to an 'other-directed' individual who internalizes the perceived norms and values of an idealized, general peer group not necessarily like people living nearby. In his writing, Riesman used the term postindustrial society to connote growing importance of leisure over work and specifically growth of leisure as a central value of lifestyle. Similarly, sociologist Ralf Dahrendorf (1959) described how – in what he termed emergent 'postcapitalist' societies – occupational roles would lose their ability to comprehensively mold the social identity of workers as other spheres of individual and collective behavior took on greater importance.

Continuing in this vein, sociologist Dean MacCannell (1976) asserts that elements of leisure, in the realm of consumptive behavior, may now dislodge work as an organizing force behind social arrangements of contemporary society. Specifically, MacCannell holds that the domain of work has exhausted what he described as a capacity for 'regeneration' such that new forms of social organization would no longer materialize in the realm of production. According to Dean MacCannell (1976: p. 6), 'Lifestyle,' a generic term for specific combinations of work and leisure, is replacing 'occupation' as the basis of social relationship formation, social status, and social action."

Such a vision proposes that advances in automation and productive capacity of science – realized through technology – will together supplant the work ethic with an emphasis on leisure as source of personal and collective meaning. This resonates with the notion that in a postindustrial socioeconomic order, the immaterial conception and marketing of goods, as well as the broad means through which they are channeled to consumers, diminishes the social importance attributed to production and the work associated with it. Daniel Bell (1973: p. 348) provides a simple causal factor for this transition from social value being placed in productive activities to it being placed in consumptive activities in his singular statement that "A postindustrial society is one in which the majority of those employed are not involved in the production of tangible goods."

As a management consultant, the self-styled 'social ecologist' Peter Drucker (1969) is typically credited with early recognition of key aspects of what many now refer to as the New Economy in his description of an ascendant class of 'knowledge workers' and, indeed, arrival of a 'knowledge society.' References to 'new economy' may serve as a sometimes alternative reference to the postindustrial and is used to describe an extensive revision of the established paradigm of a capitalist economy. Like others attempting to describe socioeconomic changes over the past several decades, Peter Drucker (1993: p. 8) described an emergent society based on this new economy as one in which "the basic economic resource – 'the means of production,' to use the economist's term – is no longer capital, nor natural resources, nor 'labor.' It is and will be knowledge." Similarly, the sociologist Alain Touraine (1988: p. 104; see also Touraine, 1971) states that "The passage to postindustrial society takes place when investment results in the production of symbolic goods that modify values, needs, representations, far more than in the production of material goods or even of 'services.' Industrial society had transformed the means of production: post-industrial society changes the ends of production, that is, culture."

While defining oneself by way of a job might have been something embraced by urbanist and writer William Whyte's (1956) memorable character, the 'Organization Man,' who as corporate employee not only worked for but also – effectively and affectively – belonged to 'the Company,' social scientists such as Richard Sennett (1998) assert that the economic conditions of a new culture of capitalism – one that reshapes the very nature of work – provide no guarantee of stability in one's job as a source for self-definition. While such ambiguity is not new, Richard Sennett (1998: p. 31) explains that when compared with any other time in history, uncertainty in the 'flexibility' that appears to characterize a postindustrial society is peculiar only by virtue of the fact that it "is woven now into the everyday practices of a vigorous capitalism. It is meant to be normal."

Departing from the ideal of a standardized, Fordist industrial world, today's worker must exhibit flexibility by being malleable and forever learning. The cultural historian, John Gillis (1996: p. 232) suggests that in the postmodern era, postindustrial societies encourage people of all ages "to think of themselves in a perpetual state of becoming … [who must] retrain, re-educate, and recycle." One of the defining features of a postindustrial society may be that workers are expected to see themselves as a set of disembedded skills rather than as a complete, integrated individual with a particular, discrete job.

At a time when economic restructuring had roiled the US economy, the term 'contingent work' was coined by Audrey Freedman (1985: p. 35), an economist at the US Bureau of Labor Statistics, to describe "conditional and transitory employment arrangements as initiated by a need for labor – usually because a company has an increased demand for a particular service or a product or technology, at a particular place, at a particular time." As companies moved to what came to be known as 'just-in-time' manufacturing during the 1980s, it was only a short step to begin following a model of just-in-time employment. Employers today increasingly want what are variously referred to as 'portfolio workers,' 'career gypsies,' 'project workers,' 'temps,' and 'task consultants' to do specific but transitional work.

The term 'free agent' has been used to characterize a growing number of workers who are in some manner working for themselves and living lives documented by social commentator Daniel Pink (2001) in his popular book *Free Agent Nation: The Future of Working for Yourself*.

While Pink and others suggested a postindustrial society composed of the *de facto* self-employed, some envisioned a world without workers. Declaring that the 'Information Age' had arrived through advances in information technology and communication, economist Jeremy Rifkin (1995) held that 'intelligent machines' would promote eventual elimination of human labor from production processes and usher in a 'near-workerless' world. In his book, *The End of Work*, Rifkin (1995: pp. 56, 293) asserts that while "the century-old utopian dream of a future techno-paradise is within sight," its arrival would not come without potential peril for he also warns "the end of work could spell a death sentence for civilization as we have come to know it." Having been transformed by changes in the world of work, Rifkin proposed that postindustrial societies must provide productive outlets for displaced human labor through work in a 'third sector' that would stand apart from either private or governmental sectors of the economy. This would be a realm of nonprofit, voluntary, community-based work basic to civil society. In Rifkin's view, with governments abandoning their long-standing position as backup employer and with a formal, private sector increasingly ineffective at creating enduring jobs for millions of people in search of employment all over the world, it is necessary to reimagine work itself through developing a robust third sector to absorb workers displaced by economic and governmental restructuring. Thus, postindustrial society would be one built out of the need to address the fundamental problem of widespread unemployment.

Some theorists point to a shift from what Lash and Urry (1987) refer to as 'organized capitalism,' characteristic to the mid-twentieth century, to a 'neoliberal' form of (late) capitalism. Important in this move is the end of Fordism as a framework for defining the relationship between capital and labor. Specifically, while under Fordism – born in the industrial sector of the economy – organized labor fared reasonably well in terms of pay and job security, in the neoliberal, post-Fordist socioeconomic order, workers are contingent, disposable. At the same time, Keynesian principles for the relationship between the economy and government are thought to have shifted from one of regulation and investment in social programs to deregulation and disinvestment – a trend that may be seen as either challenging or hastening fulfillment of the vision outlined by Rifkin.

Tensions and Competing Visions

Given that rapid urbanization has been tied in large part to the growth of industrial economies during the previous two centuries, processes of deindustrialization within developed countries – understood as variously linked to the emergence of postindustrial society – have contributed to declining economic opportunity and outmigration from urban areas in most regions formerly dependent on large industrial employers. Thus, in light of economic restructuring leading to the closure of these factories, planning and policy discussions in the United States regarding urban and regional development often associate postindustrial society with alternative models for growth and, specifically, attempts by those communities most affected by deindustrialization to attract and retain residents as well as economic capital. The prevailing approach to encouraging capital investment in many such places has been to cut taxes and provide cheap land and labor in order to attract big employers. It is this 'smokestack chasing' strategy – as it is sometimes called – that various communities now challenge in their attempt to usher in a postindustrial economy, at least at the local level, and assure some stake in what is taken to be emergence of a broader, postindustrial society.

Many towns and cities in the northern tier of the midwestern and northeastern United States that collectively comprise what many refer to as the Rust Belt – in order to conjure images of decaying industrial places from another economic era, have embraced the promises of New Urbanists and others. At the core of their planning prescriptions is a call to create 'healthy neighborhoods' defined by walkable scale, open spaces for public recreation, a range of housing options and businesses in 'mixed-use' design, and a 'sense of place' that evokes traditional, human-scale urbanism. Proponents assure economic benefit from such development through attracting an emergent social demographic referred to as 'cultural creatives' by sociologist Paul Ray and psychologist Sherry Anderson (2000) and by urban studies theorist Richard Florida (2002) as the 'creative class.' For former industrial places, the image of a postindustrial society is taken as an ideal to achieve through nurturing such 'creatives' for whom community development refers to enhancements in quality of life enabled by way of progressively vibrant and diverse economic and social environments.

For some, postindustrial society promises a world wherein traditional social and cultural boundaries might be transcended. Perhaps reproducing a technocratic 1950s confidence and sense that modernization would make possible what seemed – following the war – a necessary break with an outmoded and menacing past, late-twentieth-century futurists held that the new nature of capital would provide everyone equal opportunities to benefit from developments in information and technology and lead to an emphasis on educational achievement. Further, a fundamental reliance on human – rather than natural – resources and capital would place less strain on the environment as the very character of work shifted even farther away from a direct confrontation with nature.

Alvin Toffler's (1980) book *The Third Wave* might be considered an expression of this broadly idealized vision of postindustrial society. Reflecting an understanding that human history could be understood in terms of two previous 'waves' entailing the agricultural and industrial revolutions, Toffler projected an incipient wave that would radically transform the world of work and end the dehumanizing effects of industrial labor so maligned by Penty and others. Toffler forecast creation of a distinctly postindustrial lifestyle that would be rooted in an idealized, pastoral landscape where workers could relocate from overcrowded and often fractious metropolitan areas for quality of life considerations while remaining electronically connected to service- and

information-based jobs located elsewhere. These postindustrial workers would value careful use of resources and environmental protection. In his studies of migration trends within the United States, economist Jack Lessinger (1986) suggests that in postindustrial society one will see a category of person appear that he terms the 'caring conserver' who is born of dissatisfaction with status quo values that define fragmenting relationships of work, family, and community that have characterized industrial society, generally, and American suburbia, in particular. In his view, the suburb will fall to a vast, deconcentrated 'penturbia,' as he brands the nonmetropolitan areas of the country, through the force of changing consumer tastes.

For those with far less boosterish views of postindustrialism, the relatively utopian visions offered by Toffler and others grossly exaggerate the transformative, leveling powers of information. For these theorists, the intellectual demands necessary to be competitive – coupled with ever-decreasing demand for manual forms of labor – would put currently marginalized groups at even further social and economic disadvantage and serve to deepen existing achievement gaps. Thus, historically advantaged groups who would take the lead in developing new information-based, service industries could maintain their economic, social, and cultural privilege. Generally in the pessimistic camp, Alain Touraine held that the benefits of education and knowledge would continue to be unevenly distributed among members of society and, further, that one would likely see conflict grow between those whose knowledge embodied humanistic principles and those who purposefully developed what were now more socially valued scientific and technical forms of knowledge.

Not only would social class remain an influence in educational opportunity within developed and developing countries alike, but differentiation in opportunity and access would also be deepened as historically poor countries were left unable to catch up given the rapid pace of change. In this sense, postindustrialism would be based on emergence of a highly developed and fundamentally unequal division of labor internationally in which established industries could transfer their production (and other) processes. In the 1980s, the term 'outsourcing' (like 'downsizing') joined American speech and tellingly described the turn to contracting out certain elements of business. Later, the term 'offshoring' emphasized wholesale relocation of certain functions out of country. According to geographers Allen Scott and Edward Soja (1996), although major sites of industrial production may lie largely outside of those countries that could be labeled postindustrial, their societies remain fundamentally bound to industrial production as a basic engine of growth and focus for processes of capital accumulation. Such an assessment identifies service sector expansion in the developed world with redistribution of manufacturing jobs to relatively low-cost and regulatory-lax developing countries in Asia and Latin America. In this interpretation, one could expect the traditional compromise of industrial capitalism between social and environmental justice and economic productivity to continue.

Basically, the comparatively dystopian perspective on postindustrial society lends itself to the assertion that it is wrong to hold that information-based capitalism is in any way meaningfully different than its forebear in industrial capitalism. From this viewpoint, extant postindustrial economic organization can only reproduce a capitalism fraught with persistent problems tied to class struggle and inequality rather than usher in a fundamental transformation of society. Thus, while it became accepted practice in the 1990s to refer to Eastern Europe as 'postcommunist,' virtually no scholar has embraced the term 'postcapitalist,' applied by Ralf Dahrendorf (1959) decades earlier as a label to describe Western Europe. Peter Drucker (1993), however, is a notable exception in his insistence that a rise of the knowledge worker must challenge the understanding of capitalism given that these workers have ownership of the means of production in the form of their accumulated education, ideas, and skills. One can see that this, at least partly, is a reflection of Dahrendorf's position that he was witness to a shift in 'authority relations,' of power, from control of the means of production, or property generally, to managerial and administrative control of capital. At the same time, however, Drucker nevertheless describes a society that continues to be defined by a basic dichotomy – a class division – between an educated elite of 'knowledge workers' and those that toil without comparative education, skills, or autonomy as 'service workers' in conditions not fundamentally different from those of the scientifically managed assembly line.

In *The McDonaldization of Society*, sociologist George Ritzer (1993) speaks to the split between classes of workers described by Drucker by centering on the milieu of legions of service workers. Ritzer reconceptualized Max Weber's arguments about the bureaucratic organization of society through applying his model for the fast-food industry wherein four primary components are efficiency, predictability, calculability, and increased control through replacement of human labor and capital with technology. Ritzer holds that the profitable operationalization of these components leads to further rationalization of basic forms of human interaction and broader social structures in both the economic and social spheres. Ritzer's position is that principles employed in the fast-food restaurant – a major component of the service sector – would come to dominate many aspects of society far from their origins in those businesses. That the components of McDonaldization demand organizationally defined efficiencies, highly quantified assessments, maintenance of systemization, formalization, and routine, and a rigid concern for managing corporate uncertainty, challenges assertions that societies in the developed world can be properly described as 'post-Fordist.'

The historian Christopher Lasch (1972: p. 47) argued that "The post-industrial order, far from transcending the contradictions inherent in capitalism, embodies them in an acute form." In his review of Bell's *The Coming of Post-Industrial Society*, Christopher Lasch (1974) contends that Bell posited a simplistic sequence of social development in which a postindustrial society summarily replaces a fundamentally capitalist, industrial one. This would suggest that Bell assumed that society developed through distinct phases and that industrial capitalism was but one of them, in manner akin to Karl Marx. In fact, Bell was quite critical of Marxist insistence on a binary class system and suggested, for example, that companies were increasingly owned by a fluctuating assemblage of shareholders – to whom they

must ultimately answer – rather than a singular class of wealthy individuals. In his new foreword to a revised edition of his book, Daniel Bell (1999: p. xv) referred to this as an economic, if not social, system wherein one approached the anomaly of having 'capitalism without capitalists.'

Examining restructuring of the economic system during the 1980s in developed countries like the United States, Manuel Castells (1996) described a rise of what he described as 'informational capitalism,' the creation of 'network society,' and the 'feminization' of work. In his book *The Rise of Network Society* (1996), the first of a triology titled *The Information Age: Economy, Society and Culture*, Castells spoke of how networks were becoming a key feature of 'social morphology,' and would serve as basic units of postindustrial societies. In these emergent social arrangements, 'networking logic' not only modified the operation and outcomes of production – through technological change and a shift from vertical bureaucratic structures to decentralized, horizontal organizations – but also informed cultural changes associated with networking. Transcending space and time in a capacity for pervasive, perpetual communication, Castells holds that the contemporary global economy is founded on instantaneous flows – a so-called space of flows wherein economic and cultural capital are exchanged – that shape both productive processes and patterns of consumption. Many social observers point to ways in which 'social networking' made possible by forms of so-called new media – as might be seen in the use of Facebook or Twitter – can be taken as illustrations of how network society organizes and, in particular, how this organization can take place outside the control of state apparatus.

Within this emerging socioeconomic order, Castells (2000: p. 12) describes how the "flexible woman gradually replace(s) the 'organization man' as the harbinger of a new type of worker" as well as transforms existing social relationships through redefining such basic categories as gender, family, and sexuality. Despite this possibility for transformation, like Drucker, Castells maintained that a fundamental divide would remain among classes of workers. In the networked society, this divide exists between 'informational' or networked labor – workers who are 'self-programmable,' adaptable, highly educated, and skilled at managing information – and 'generic' laborers, such as those in the service sector, who are relatively deskilled, exchangeable, and disposable.

Although quite a number of theorists of postindustrial society have advanced the primacy of knowledge and information not only as basic to the conduct of contemporary business but also as fundamental principles for social organization, it may be argued that the basic values of capitalism – even if described, perhaps, as 'late-capitalism' – determine what kinds and by what means informational media, knowledge, and technology are produced, distributed, and consumed. The postmodern cultural logic of a late capitalism has been described by Frederic Jameson (1984) and others as fundamentally derived from an emphasis on fragmentation, commodification, acceleration, and simulation that threatens a controlling influence in all spheres of contemporary life. Speaking on this control, the social theorist Jean Baudrillard (1980: p. 137) referred to postindustrial society as one dominated by a 'neo-capitalist cybernetic order' of electronic media where "we live in a world of proliferating information and shrinking sense" that effectively damages the existing social order by destroying the 'real' and substituting 'simulacra,' complex simulations that provide spectacle instead of meaning. For his part, Jameson (1984: p. 78) insists that the consumer capitalism that characterizes a possible postindustrial society is "the purest form of capital yet to have emerged, a prodigious expansion of capital into hitherto uncommodified areas."

Over a century ago, Emile Durkheim envisioned that 'mechanical solidarity' among members of preindustrial societies was transformed into an 'organic solidarity' among members of industrial societies that was shaped by an elaborate division of labor accompanied by a system of rights and duties that bound people together in an enduring fashion. While acknowledging a global shift to economic postindustrialism, the economist Daniel Cohen (2009) wonders whether it is possible to herald a postindustrial society when the Durkheimian solidarity that characterized industrial society appears lost to systematic disassembling of the components of large industrial enterprises, increasing contractual or contingent work, and the physical and structural distancing of workers from each other. In a similar manner, Eric Hobsbawm (1994: p. 334) writes that "The cultural revolution of the later twentieth century can thus best be understood as the triumph of the individual over society, or rather, the breaking of the threads which in the past had woven human beings into social textures."

Concluding Thoughts

There appears a fundamental tension in thinking about the possibility for a postindustrial society. There are those who appear ready to embrace the term 'postindustrial' when applied to the economic sphere, but decline to assert arrival of post-industrial society. On the other hand, others are disinclined to describe any society as economically postindustrial given that they find industrialism remains essential to the global economic system of which all societies are a part.

The term 'postmodern' has generally been applied to discussions of present-day culture – as opposed to society – and typically refers to how the status of knowledge has been altered through the peculiar qualities of a form of capitalism that may be distinct from that of a widely industrial age. It is generally believed, by those applying the term, that this is about much more than a shift from an economic order based on production of goods to one based on production of knowledge. Rather, it entails fundamental changes in the nature of knowledge itself and attendant changes in the footings for social organization through evolving conditions of labor and, indeed, the very meaning and place of work in contemporary culture and society. While industrial society transformed the means of production through the large-scale assembly of standardized, material goods, what may be characterized as the 'post-industrial' appears to transform culture through the production of symbolic goods, ascendance of media, and emergence of mass society.

Postmodern Urbanism

This article is a replacement of the previous edition article by M.J. Dear, volume 17, pp. 11856–11860, © 2001, Elsevier Ltd.

Abstract

Beyond signaling a departure from the tenets of modern urbanism, postmodern urbanism remains an essentially contested concept. Shooting to fame in the 1980s and 1990s, it was greeted by many as a new urban logic, forged as modernity's future-oriented temporality yielded to a postmodern concern with spatiality. Yet the postmodern transformation of the city was dismissed as capitalism's new 'cultural clothing' by urban political economists. Paradoxically, the term's premature disappearance may signal its triumph rather than its demise, the situation it was meant to grasp perhaps becoming generalized to the point where the need for specialist terminology is rendered redundant.

Defining the Indefinable

Postmodern urbanism, like the 'postmodern' itself, remains an essentially contested concept. One might superficially define it in terms of an urban form that defies the predictable ordering principles and expected land-use patterns of the modern city (such that Los Angeles is typically cited as the paradigmatic postmodern city, in contrast to that modern urban archetype, Chicago) (Dear, 2000; Soja, 1996). Or one might relate the concept to an architectural aesthetic that playfully subverts the modernist logic of 'form following function' (Ellin, 1996). Or, indeed, one might allude to the kind of 'disorientating' urban environment that results from either or both of the above, noting the iconic status of Los Angeles's Bonaventure Hotel in this regard (Jameson, 1984). Or, again, given that the world of art and letters invariably functions as the vanguard of theory, one might gesture, with Harvey (1989), toward the urban sensibilities captured in a book like Jonathan Raban's 'Soft City' or point to a film such as Ridley Scott's 'Blade Runner' (particularly when the latter is contrasted with the archetypical modern city of Fritz Lang's 'Metropolis'). Such superficial definitions are useful, but only up to a point.

To say that postmodern urbanism is essentially contested is to say that it is impossible to provide a single, universally accepted definition. The term is invoked in innumerable ways, the diversity of meaning arising from the fact that interpretations may vary along at least three different dimensions: first, in relation to the various senses attributable to the term 'postmodern' (principally, whether one accepts that the authority of so-called 'metanarratives' has been undermined (Lyotard, 1984) or not (Harvey, 1989), which effectively amounts to accepting or rejecting the postmodern thesis per se); second, in terms of the way in which modernity and postmodernity are configured in relation to space and time (some align modernity with temporality and postmodernity with spatiality (Soja, 1989), while others reject such formulations); and, third, with regard to how the urban itself is conceived (in broadly sociospatial terms, for instance (Dear, 2000), or primarily in architectural terms, relating to the built environment and urban landscape (Ellin, 1996; Ley and Mills, 1992)). The combinatorial possibilities arising from these differences would be enough to grant 'postmodern urbanism' significant semantic complexity. Add to this the incompatibility of certain combinations, and one can readily appreciate the definitional difficulties it presents.

Whenever definitions of postmodern urbanism are offered, they generally help to clarify the term's meaning, yet cannot but reveal the predilections of those proffering the definitions. Thus, for Dear (2000, 140), the problematic of a distinctively postmodern urbanism "is based on a simple premise: that just as the central tenets of modernist thought have been undermined, its core evacuated and replaced by a rush of competing epistemologies, so too have the traditional logics of earlier urbanisms evaporated, and in the absence of a single new imperative, multiple urban (ir)rationalities are competing to fill the void." As helpful as this may be, when Harvey (1987, 279) refers to postmodern urbanism in relation to the American city as "nothing more than the cultural clothing of late capitalism," it is implicitly understood that the alleged undermining of the 'central tenets of modernist thought' in favor a 'rush of competing epistemologies' is something calling out for explanation, not something to be regarded as an explanation in its own right.

"Discourses of the postmodern are having profound effects on a range of urban practices, from philosophy to planning," wrote Gibson and Watson (1995, 1), in a major collection on the topic released at the height of its influence: "It would seem that, whether we like it or not, the postmodern is here to stay." As it turned out, nothing could have been further from the truth. Despite the intense debate constituting an initial period of engagement with the topic, the term has, by now, been largely abandoned. One should, however, interpret its disappearance with caution. Though the terminology may have run its course and fallen out of favor, this may signal the concept's triumph as much as its demise, the situation that it was meant to grasp having become so generalized as to render the need for specialist terminology redundant.

The City in Ruins

Postmodern urbanism is predicated on the idea of the 'end of modernity.' A direct corollary is that the modern city, one of

modernity's crowning glories, lies in ruins. An immediate note of caution should be sounded here, however, for neither the notion of 'the end' nor the sense of 'ruination' is quite what it seems. Let us take each in turn. The hypothesis of the end of modernity signals something other than a conventionally understood terminal point, of the kind that might be located at the far end of a linear trajectory. Insofar as the notion of linear time, progressing toward some distant (utopian) location in the future, is itself a thoroughly modern one, then the end of modernity would also signal the end of linear time – and with it the end of the illusion of 'the end' itself. This leaves us trapped in the endless repetition of a 'perpetual present' that some call schizophrenic. The end of modernity, therefore, equates to the 'end of history,' inasmuch as history ineluctably belongs to the world view instated by modernity (and not the other way round). The idea of a linear chronology is itself perfectly modern. Holding to it in interpreting the end of modernity would be self-defeating, since it necessarily entails that modernity's uninterrupted progress is still in train, thereby undermining its own reasoning or begging the question (petitio principii).

Similarly disrupting conventional meanings, the idea that the fate of the city after modernity is one of ruination is far from a straightforward allusion to physical decay and decrepitude, even if the rhetorical force of such tropes sometimes finds favor. The dystopian Los Angeles of 2019 envisioned by Blade Runner, for example, was in perfect accord with the postmodern thesis in view of its uncompromising departure from modernist fantasies of a utopian urban future. Yet, in keeping with the contradictory qualities of the postmodern, a sense of ruination may just as easily be derived from precisely the opposite point of view: in terms of the loss of any solid, authentic reality in favor of the superficial glitz or insubstantial froth (Soja, 1996, 247) speaks of 'bubbling, postmodern complexity' associated with the postindustrial city, the consumer society, gentrification, urban boosterism, image-driven place promotion accompanied by a thin veneer of soulless regeneration, and so on. For Marxist urban scholars, especially, such processes stand accused of sanitizing the real, gritty urban environment, replacing it with a fantasy construct, detached from workaday lives of the silent majority, and expressing the privileged vision of a yuppified urban elite (Harvey, 1987). Marxists do not intend to romanticize the alienating dead weight of the modern city, of course, as much as expose the 'castles in the air' of a fake postmodern utopia. However much the 'end of modernity' signaled by the postmodern thesis problematizes the idea of the end, in Marxist circles this involves a surreptitious defense of an indefensible concept, illegitimately sidestepping the need to examine its veracity.

A key facet of the discourse of postmodern urbanism, which made it central to the postmodern debate as a whole, is that a major attempt to fend the notion off was provided by the foremost Marxist urban scholar, David Harvey (1989). Harvey (1987) initially examined postmodernism in relation to the American city, assembling a wealth of evidence to account for the latest round of 'postmodern' urban transformations as expressive of a new capitalist regime of 'flexible accumulation' – a regime emerging from the demise of the preceding Fordist regime of mass production, mass consumption, and Keynesian demand management. Accordingly, for Harvey (1989), there was something suspect in the postmodern thesis propounded by Jean-François Lyotard (1984), insofar as it sought to rule out of court the kind of explanation Harvey offered, suggesting that it had been 'delegitimized' by the very changes he sought to explain. The inherent circularity of the argument is giddying. To invoke another metaphor, it bears all the hallmarks of an intractable debate; a confrontation of the 'irresistible force meets immovable object' variety. Lyotard included Marxism among the modern 'metanarratives' whose legitimacy had been undermined by the changing nature of knowledge. For Harvey, such pronouncements are themselves explicable in terms of the Marxist 'metanarrative,' which unveils them as prime instances of ideological obfuscation: good, old-fashioned false consciousness. Let us take this more slowly, first putting forward Lyotard's case, then returning to Harvey.

Lyotard (1984, xxiv) defined the postmodern as 'incredulity toward metanarratives.' Whereas, once upon a time, stories were simply stories, at the Enlightenment, certain discourses were elevated to previously unknown heights, granting them unprecedented legitimacy on account of their privileged access to the truth. Knowledge, it was claimed, could lead humanity on the road to emancipation (knowledge serving as a means to an end); to a full and final understanding of reality itself (knowledge serving, here, as its own, 'speculative' end). For Lyotard, there is no question that knowledge could ever actually provide access to the real (as promising as the emancipatory rhetoric sounds). One can never dive down beneath language to see directly how well it maps on to reality: metanarratives merely sustain the belief that one can. Metanarratives were a way of modern knowledge legitimating itself, precluding other, potentially competing 'language games' from measuring up against its declarative pronouncements. The fact that this thesis is even possible might suggest a waning faith in the power of modern knowledge. Add to it the ever-growing toll of modernity's unintended consequences, the countless atrocities and injustices committed in its name, the damage done by those claiming to act on the authority of the truth, and the Enlightenment blueprint of progress-through-knowledge begins to lose its former allure. Lyotard (1984) merely ruminated on the fact that knowledge today occupies a wholly different position from the one it enjoyed throughout modernity, where the alignment of knowledge and power had reigned supreme. If modernity solemnized the marriage between power and knowledge – producing a reciprocally reinforcing 'power/knowledge:' knowledge-assisted power coupled with power-assisted knowledge – then postmodernity presides over the divorce. Lyotard (1984) saw nothing to lament in this state of affairs. Modern metanarratives had always gained legitimacy by delegitimizing other, competing narratives ('paralogies', if you will). For Lyotard, a strict adherence to realism and the regulative ideal of true knowledge necessarily did violence to the other. Even emancipatory projects, such as historical materialism, occluded the possibility of sensing the many other injustices that were simply not permitted to appear within a given frame of reference. (Interestingly, Harvey's (1989) defense of the Marxist frame of reference created a backlash from feminist scholars, who saw the potential of

a 'postmodernism of resistance' that might embrace more than class struggle alone.)

Historical materialism, in seeking to shape a better world on the basis of privileged access to the truth of history, meets all of Lyotard's criteria for a metanarrative. One can see why Marxists would demur. A fundamental principle of historical materialism is that social consciousness itself is a reflection of the material mode of production of society, and not the other way round: knowledge forms a part of the ideological superstructure, arising on the base provided by the mode of production. On this understanding, tracing a cultural logic back to its economic determination seems a robust tactic, not least where the capitalist mode of production is concerned. For Harvey (1989), this provides sufficient ammunition to demonstrate that his own favored metanarrative (so-called) remains fully operational: not least in that it is eminently capable of exposing the sort of ideological discourse that would aim to undermine its credibility. Harvey thus turns the tables on Lyotard, putting postmodernism in the dock, precisely where Lyotard had placed Marxism. There is, however, a significant blindness in reactions to the postmodern that saw it as a superficial, 'merely cultural' phenomenon – yet no more so than there is in those who misguidedly regarded the 'postmodern' as marking a complete break with the past, as much 'postcapitalist' as 'post-' anything else. In retrospect, the postmodern debate demonstrates that an attitude of 'business as usual' for Marxist urban theory represented an inadequate response (Dear, 2000), while those seeking to maintain a clean break with modernity – especially evident in attempts to periodize modernity and postmodernity as epochal concepts – were on a hiding to nothing.

Urban Revolutions

Postmodern urbanism juxtaposes a profound discontinuity – the end of modernity – with a marked continuity – the survival of capitalism. Much of the debate rehearsed above was premised on a false choice between the two. In this regard, it is unsurprising that the resources offered by another Marxist, Henri Lefebvre, should be called upon to conceptualize postmodern urbanism, most notably by Ed Soja (1989, 1996, 2000). While some have (not unreasonably) objected to the postmodern appropriation of Lefebvre (Kipfer et al., 2008), it is undeniable that Lefebvre's (2003) work prefigured the tenor, if not the tenets, of postmodern urbanism. Originally published in 1970, that work was forged in the aftermath of the events of May 1968, which exposed the French Communist Party's willingness to subjugate spontaneous revolutionary desire to a self-interested concern with establishing power on its own terms. Lefebvre's titular 'urban revolution' may be read, on the one hand, as the twentieth-century counterpart of the nineteenth-century industrial revolution and, on the other hand, as a recognition of an epistemological revolution accompanying the arrival of a fully urbanized society. "The words 'urban revolution' do not in themselves refer to actions that are violent. Nor do they exclude them" (Lefebvre, 2003, 5).

Urban space has, for Lefebvre, become a crucial locus of difference; of that which is not recoupable to any established order. In Lefebvre's (2003, 37) words, the urban revolution "is constituted by a renewed space-time, a topology that is distinct from agrarian (cyclic and juxtaposing local particularities) and industrial (tending toward homogeneity, toward a rational and planned unity of constraints) space-time. Urban space-time, as soon as we stop defining it in terms of industrial rationality – its project of homogenization – appears as a differential, each moment existing only within a whole, through the contrasts and oppositions that connect it to, and distinguish it from, other places and moments." For Lefebvre (2003, 38), isotopy (a term expressing linguistic redundancy, borrowed for the purposes of 'reading' space), refers to 'everything that makes a place the *same place*.' Heterotopy, in contrast, turns it into a different place, another place: securing its difference by ensuring that it differs from itself. Both these notions apply to real places, rather than to imaginary or symbolic places like utopia or its negative double, dystopia. They signal, however, the inherently contested nature of space, its dialectical charge.

In a subsequent work, originally published in 1974, Lefebvre (1991) elaborated and refined this idea, formulating two conceptual triads to grasp the different 'moments' of the production of space: 'spatial practice,' 'representations of space,' and 'representational spaces,' which may be assimilated to the phenomenological realms of the 'perceived' (*perçu*), the 'conceived' (*conçu*), and the 'lived' (*vécu*). The emphasis placed on production relates to Lefebvre's insistence on space as a concrete abstraction – an abstraction whose truth is forged in practice – and on its ineffably 'open' quality, which derived from its ceaseless production. "The original sense of 'production,' as Baudrillard (1987, 21) reminds us, "is not in fact that of material manufacture; rather, it means to render visible, to cause to appear and be made to appear: *producere*." If space is produced, it is never static, and it is produced differently at different times and by different societies. In an oft-cited passage, Lefebvre (1991) adumbrates the crisis of a specifically modern space – the sort of ordered space, predisposed toward surveillance, that finds its origins in the Quattrocento space of perspectival art. Here, the extent to which Lefebvre's concerns foreshadow postmodern urbanism again becomes apparent:

> The fact is that around 1910 a certain space was shattered. It was the space of common sense, of knowledge (*savoir*), of social practice, of political power, a space thitherto enshrined in everyday discourse, just as in abstract thought, as the environment of and channel for communications; the space, too, of classical perspective and geometry, developed from the Renaissance onwards on the basis of the Greek tradition (Euclid, logic) and bodied forth in Western art and philosophy, as in the form of the city and town. … Euclidean and perspectivist space have disappeared as systems of reference, along with the other former 'commonplaces' such as the town, history, paternity, the tonal system in music, traditional morality, and so forth. This was truly a crucial moment (Lefebvre, 1991, 25).

When Lefebvre's erstwhile assistant at Nanterre, Jean Baudrillard (1987, 126) – later dubbed the 'high-priest' of postmodernity – declared that "There is no more system of reference to tell us what happened to the geography of things," the resonance is clear. Their views of the world, however, are far from consonant. While Lefebvre is concerned

to trace the contours of a spatial dialectic, for Baudrillard (1990a, 7), "the world is not dialectical, it is sworn to extremes, not to equilibrium; sworn to radical antagonism, not to reconciliation or synthesis."

The incautious treatment of such resonances will, as we shall see, prove deleterious to framing postmodern urbanism as a meaningful discourse. Bearing this in mind, it is noteworthy that Lefebvre's (2003) articulation of 'differential' space in terms of the 'heterotopic' chimes with Foucault's (1986, 25) 'heterotopia,' the topic of a 1967 lecture. Heterotopias – Foucault's examples include cemeteries, theaters, brothels, colonies, ships, hotels, and gardens – are "capable of juxtaposing in a single real place several spaces, several sites that are in themselves incompatible" (Foucault, 1986, 25). Foucault's opening remarks, moreover, bear an uncanny resemblance to the thesis of The Urban Revolution:

> The great obsession of the nineteenth century was, as we know, history: with its themes of development and of suspension, of crisis and cycle, themes of the ever-accumulating past, with its great preponderance of dead men and the menacing glaciation of the world. … The present epoch will perhaps be above all the epoch of space. We are in the epoch of simultaneity: we are in the epoch of juxtaposition, the epoch of the near and far, of the side-by-side, of the dispersed (Foucault, 1986, 22).

The proximity of Foucault's and Lefebvre's formulations should not, however, blind us to their differences. Foucault's concern to relativize history is, somewhat impishly, turned by Lefebvre (2003, 191) into a symptom of the 'urban revolution' (just as Foucault might see Marx as symptomatic of the industrial revolution): "Using borrowed concepts and terms we can say that the urban … rises above the horizon, slowly occupies an epistemological field, and becomes the episteme of an epoch."

> During this new period, what once passed as absolute has become relativized: reason, history, the state, mankind. We express this by saying that those entities, those fetishes, have died. There is something true in this claim, but fetishes do not all die the same death. The death of 'man' only affects our philosophers. … Reflective thought allows itself to be captivated by these dramas and turns its gaze from the field before it, which remains blind. To explore this field, to see it, change is necessary, the abandonment of earlier viewpoints and perspectives. During this new period, *differences* are known and recognized, mastered, conceived and signified (Lefebvre, 2003, 36–37).

Foucault is implicitly castigated for scotomization, for a misdirected, 'reflective' thought, out of step with a society in the throes of urban revolution – streetwise and attuned to difference – that is already detecting unfamiliar shapes emerging in a visual field from which the philosophers avert their gaze. Could Lefebvre's work amount to a postmodern urbanism avant la lettre? This implication is explored in an ambitious exegesis of postmodern urbanism presented in a trilogy of studies by Soja (1989, 1996, 2000).

Soja's dazzling, eclectic performances are justly famous for, among other things, juxtaposing Foucault and Lefebvre. A good deal of fancy footwork, however, makes it extremely difficult to keep one's eye on the ball, and their success belies some pervasive problems. Soja privileges difference to the extent that anything goes, including substituting the dialectic with the neologism 'trialectic' – the result, unfortunately, being equally unsatisfactory to dialecticians and postmodernists. "Noting the recurrent use of conceptual triads in Lefebvre, Soja reifies them into 'trialectics' (sic) of ontology (spatiality, historicity, sociality) and epistemology (first, second, third space)," observe Kipfer et al. (2008, 20): "Lefebvre's triad of the production of space is transformed into an 'epistemological trialectics' of objectivist (first), subjectivist (second), and lived (third) space." For Soja (1996, 56–57), "*Everything* comes together in Thirdspace: subjectivity and objectivity, the abstract and the concrete, the real and the imagined, the knowable and the unimaginable…" and so on. Establishing itself on an etymological simplification invoking the binary, however, Soja's remedial 'trialectic' manages to miss the complex senses of 'across,' 'through,' 'throughout,' and 'complete' possessed by the prefix 'dia-' (one might note, analogously, that 'dialogue' need not be between two people). In so doing, he neglects the significance of space being a concrete abstraction: "for Lefebvre, the third term in a triad is not an expression of trialectics but a product of three-dimensional dialectical transformation" (Kipfer et al., 2008, 20). Indeed, 'de-' and 'dis-' are the favored postmodern prefixes, implying subtraction and disjunction rather than addition (+1) and conjunction, yet Soja's (1996) preferred tactic is to adjoin everything in a 'real-and-imagined' space that leaves intact what would otherwise spontaneously deconstruct ('real' and 'imaginary' are left unscathed by hyphenation). As belated as the lesson may be, Lefebvre does not provide a template for postmodern urbanism.

Lost in Hyperspace

Were one forced to pick a single term to sum up postmodern urbanism, 'hyperspace,' with its sci-fi overtones, would admirably fit the bill. It was pressed into service by Fredric Jameson (1984), for whom postmodernism represents the 'cultural logic' of late capitalism – not merely its 'cultural clothing' but a fully integral logic, as if base and superstructure were fused by an unforeseen short circuit. Architecture is identified as the privileged aesthetic language expressing 'the bewildering new world space of late or multinational capital,' with certain examples, of which downtown LA's Bonaventure Hotel looms large, engendering a vertiginous experience that announces this 'latest mutation in space – postmodern hyperspace' (Jameson, 1984, 54, 83). Jameson's essay has received enormous critical attention. Yet despite the animus it has often attracted, it is not unreasonable that Jameson should have seen the labyrinthine layout of the Bonaventure Hotel as an apt metaphor for the disorientation induced by the epochal convulsions of postmodernity. Reminiscent of Baudrillard's reading of the Beaubourg (or Pompidou Centre) in Paris, 'hyperspace' resonates with Baudrillard's (1994) 'hyperreality' (the 'hyperreal' being 'more real than real'). However, while Davis (1985, 106) suggests that, for Jameson, the Bonaventure represents an 'impossible representation' of hyperspace – the implication being that representation is defeated by this latest

spatial mutation; that the real now resists representation and the territory can no longer be adequately mapped – Jameson's claim that the postmodern involves the transformation of reality into images is scarcely Baudrillardian. It is not that Baudrillard holds to the opposite hypothesis: that images have been transformed into reality. In fact, both hypotheses might well apply, but – Baudrillard's point – they would retroactively scramble the very terms in which they are framed. Unlike Soja's (1996) syncretic 'real-and-imagined,' for Baudrillard (1993, 72), "The hyperreal effaces the contradiction of the real and the imaginary." The terms 'reality' and 'imaginary' still have currency, but their meanings have been ineluctably altered and their indistinction assured. If postmodernity produces 'unreal' urban environments, then, it must be recognized that this 'unreality no longer implies the imaginary' (Baudrillard, 1990b, 30). 'Simulacrum' and 'simulation' are the apposite terms for describing this altered state (Baudrillard, 1994).

If the heterotopic qualities of hyperspace resist representation, this outcome was written into modernity from the off. In a fragmentary text by Borges, Baudrillard (1994) discovers an apt allegory for the project of modernity in the insane enterprise of a 1:1 scale map, which once covered the entire territory of a distant empire. Discontented with the world as it found it, modernity determined to make the world over in its own image. Not content with merely mapping the world, modernity resolved to change it wherever it failed to measure up to expectations: to smooth out the untidy crumples in reality; to remove the unsightly blemishes, straighten out unnecessary deviations, relocate whatever was out of place, correct any offending irrationalities: in other words, to impose order on an unruly world. In this, modernity pulled off a remarkable feat. It presented its own imaginary as the 'reality principle,' casting the world itself as its inadequate representative. In its failure to live up to the principle, reality was found wanting. Reality, therefore, was never quite what it seemed. In a classically modern move, the 'real' was forged in opposition to the 'illusory,' the 'imaginary,' the merely 'apparent.' If flighty, fickle appearances are deceptive, then solid, steadfast reality is trustworthy. What its opposing terms lack, reality possesses. Modernity's ordering zeal set out to eradicate the enigmatic, ambivalent qualities of the premodern world. Accordingly, "The true revolution of the nineteenth century, of modernity, is the radical destruction of appearances, the disenchantment of the world and its abandonment to the violence of interpretation and history" (Baudrillard, 1994, 160): not the industrial revolution, nor any other revolution, but "the immense process of the destruction of appearances (and the seduction of appearances) in the name of meaning (representation, history, criticism, etc.)." This process is, however, hoist by its own petard. The closer one gets to a world in which appearances are done away with, that world succumbs to a fatal reversibility. As appearances are vanquished, the real loses all sense of reality: not as the result of a deficit or lack of reality but in consequence of a surplus or excess: hyperreality. As with compulsory reality, so too with compulsory meaning: an excess of meaning is no longer meaningful. When something means everything, it means nothing: "by giving you a *little too much* one takes away everything" (Baudrillard, 1990b, 30). Modernity, then, is diverted from its course – not in spite of, but precisely because of, its own best intentions. Its furtive destiny lies elsewhere. Little wonder, then, that Baudrillard (1994, 160–161) should refer to the "second revolution, that of the twentieth century, that of postmodernity, which is the immense process of the destruction of meaning, equal to the earlier destruction of appearances."

From the off, modernity was on course for utopia. Even as it charted its progress, however, it went astray, "crossing into a space whose curvature is no longer that of the real" (Baudrillard, 1993, 2). The upshot is that postmodern urbanism needs to be understood, not in terms of the production of space, but in terms of its seduction – from "*se-ducere*: to take aside, to divert from one's path" (Baudrillard, 1990b, 22). Modernity inaugurated a new conception of time. In the wake of the 'querelle' of Ancients and Moderns in the 1690s, Christian Europe's time reckoning was no longer "organized around a fixed point in the slowly receding past," but was set in motion, "attaching it firmly to Europe's own thrust toward colonizing the future in the same way as it had colonized the surrounding space" (Bauman, 1987, 110). "Modernity," Bauman (1997, 86) avers, "furnished time with certain traits which only space possesses 'naturally': modern time had direction, just like any itinerary in space." Modernity was a journey; destination – Utopia. Hence the fact that 'progress' should become modernity's watchword. A future-oriented temporality, geared toward what might yet be, necessarily casts the present as inadequate. Utopia was destined to lie forever in the future, beyond the infinitely receding horizon. The secret curvature in modernity's linear trajectory, however, changes everything. The 'end of modernity' does not signal that utopia failed to appear, that society grew impatient with the arduous journey that never reached its end – but, rather, that it failed to appear in the expected location. At a certain point in time, the realization took hold that utopia was already behind us. The end of modernity signals the abandonment of the pursuit of utopia because utopia has already been achieved, no matter that it failed to materialize in the manner anticipated. An achieved utopia retrospectively reveals that utopia was never what it purported to be. Ultimately, therefore, the postmodern means not 'reaching the end,' but 'having passed beyond the end.' And beyond the end, it becomes apparent that the end no longer means anything – and never meant anything in the first place.

One should not be surprised to discover then that, beyond the end, postmodern urbanism does not look entirely dissimilar to modern urbanism. Postmodern urbanism implies in a state of hysteresis: a state defined by the continuation of the effect ('reality effects') in the absence of the cause (the 'destruction of appearances' set in sway by modernity). Insofar as it retroactively cancels out its distinction from what went before, the postmodern cannot be taken in a periodizing sense. That distinction, like the torsion in a möbius strip, occupies an indeterminate location. Only a cut localizes it, at which point it disappears, "without the reversibility of surfaces being resolved" (Baudrillard, 1994, 18). Hence Lyotard's (1984, 81) quip that the "*Post modern* would have to be understood according to the paradox of the future (*post*) anterior (*modo*)."

Zygmunt Bauman – once dubbed the 'prophet of postmodernity' – concurs:

> The 'after' bit which the concept of 'postmodernity' entailed seemed to me suspicious from the start. … It seemed to me that the 'post-modern perspective' which allowed the scrutiny of modernity's failures and the debunking of many of its undertakings as blind alleys, far from being in opposition to modernity or growing on its grave, had from the start been its indispensable *alter ego*: that restless, perpetually dissentful voice that enabled modernity to succeed in its critical engagement with found reality and the many realities sedimented by that engagement. I liked Lyotard's quip: one cannot be truly modern without first being postmodern (Bauman and Tester, 2001, 74–75).

The same logic pervades postmodern urbanism, not least in the verisimilitude of its architecture. In a manner apposite to the end of history, Koolhaas's experimental notion of Junkspace "means no more than perpetual renovation … perpetual recycling," according to Jameson (2003, 74), who cities Koolhaas to this effect: "Restore, rearrange, reassemble, revamp, renovate, revise, recover, redesign, return … redo, respect, rent: verbs that start with *re-* produce Junkspace." One could just as readily cite Tschumi (1994, 225): "dis-integrated, dis-located, dis-juncted, deconstructed, dismantled, disassociated, discontinuous, deregulated … de-, dis-. … These are the prefixes of today." There is no longer any meaningful gap between the 'de-' and the 're-': no interval capable of conferring on either a stable identity. Like characters in a cartoon caper, relentlessly chasing each other round in circles, repeatedly swapping (and ultimately losing) their identities as 'pursuer' and 'pursued,' everything loses its meaning in the vertiginous cycle of repetition. Postmodern urbanism, properly understood, defines an 'ecstatic space' (from 'ex-stasis' – to put out of place): "Ecstasy is the quality proper to any body that spins until all sense is lost, and then shines forth in its pure and empty form" (Baudrillard, 1990a, 9). To put it another way, 'postmodern urbanism' is the technical term for the city in ruins: "Hornstrumpot! We shall not have succeeded in demolishing everything unless we demolish the ruins as well. But the only way I can see of doing that is to use them to put up a lot of fine, well-designed buildings" (Jarry, 2002, 106).

Postmodernism in Sociology

Abstract

This article traces the intellectual roots of postmodernism in sociology and its evolution over the past three decades. It briefly examines the main areas of research developed as a response to the emergence of new media and communication technologies since the late 1990s. It defines postmodernism as an intellectual project developed since the 1970s mainly within philosophy and the humanities, which has been adopted, adapted, and enriched within sociology as a response to the theoretical and empirical challenges raised by the cultural features of contemporary developed societies, including here the advent of communication technologies such as the Internet. The article distinguishes between two aspects of postmodernism in sociology: the critique of theoretical assumptions considered as modernist, on the one hand, and the empirical investigation of cultural phenomena taken to be characteristic for postmodern societies, on the other hand. Empirical postmodern research has evolved from an initial dominating focus on consumption and consumerism to the investigation of 'digital cultures,' understood as communication formats such as electronic socialization platforms, instant messaging, or online gaming.

Postmodernism in sociology is an intellectual project with a controversial, yet established legacy, characteristic for the late twentieth century. This project comprises (1) an analysis of the social and cultural features of late capitalism (postmodernity), (2) a critique of sociological theory as a modernist project, (3) an extension of sociological inquiry into new domains, and (4) new forms of sociological expression. The term postmodernism made its way into sociology from literary theory and criticism in the 1970s; at the same time, its adoption continued and reformulated a series of important sociological topics. The key concepts of sociological postmodernism are subject, identity, text, and symbol. On these grounds, postmodernity is characterized as a form of social order in which the electronic media play a prominent role, symbolic codes are pervasive, and social identities are fragmented. These terms are also employed in the critique of sociological theory as a product of modernity. According to this critique, scientific theories work as symbol systems enabling certain courses of social action, and the knowing subject is the product of social circumstances. Sociological postmodernism claims a structural similarity between texts and social order: both are network-like systems of symbols. On the methodological side, sociological postmodernism emphasizes qualitative research methods, especially discourse and visual analysis. Writing-related issues also occupy an important place.

Prominent fields of postmodernist research have been the Internet, work and organizations, political action, science and technology, commodification, consumption, gender, media, and popular culture. Classical sociological topics like symbolic consumption have been further explored and enriched. During the 2000s, postmodernist research has oriented more and more toward investigating new media formats, generically known as digital cultures or as 'virtual worlds.'

Sociological postmodernism appears as a form of sociological reflection, a kind of sociological sensibility, and a specific take on a cluster of social phenomena. Its varieties share a series of theoretical and methodological premises, but differ in their conclusions and research programs. Core common elements are (1) avoiding recourse to a set of universally valid assumptions as theoretical and methodological foundations, together with (2) the key role ascribed to notions like subject, identity, text, and symbol in the analysis of society.

Origins of Postmodernism

The term 'postmodernism' has been used in Latin American literary criticism since the 1930s, and in Anglo-American debates since the 1940s, in order to designate new forms of expression in their relationship with the aesthetic of modernism. In history, the term was used by the British historian Arnold Toynbee in *A Study of History* in 1947 and designated the latest phase of Western civilization. In sociology, it was introduced by Amitai Etzioni's book, *The Active Society* in 1968. Starting with the early 1970s, the term appeared more and more frequently in sociological texts in France, North America, and the United Kingdom. At that time, it was already common stock in literary theory and criticism. An essay written by the French philosopher Jean-François Lyotard, *The Postmodern Condition: A Report on Knowledge* (1979) played a seminal role in making this term widely known and used in the social sciences. Therefore, postmodernism was partially a conceptual import; its diffusion in the 1970s was part of a wider innovative movement in the discipline, marked, among others, by the rise of social constructivism and feminism. At the same time, it continued and reformulated a series of topics already present in sociology.

The intellectual roots of sociological postmodernism can be identified in the works of some key nineteenth and early twentieth century philosophers, sociologists, and linguists. Karl Marx's critique of capitalism, Georg Simmel's analysis of modernization processes, Friedrich Nietzsche's critique of epistemology, and Ferdinand de Saussure's theory of language play here a prominent role. The French structuralist movement (Claude Lévi-Strauss's anthropology, Roland Barthes's semiotic theory, Jacques Lacan's psychoanalysis) and the post-structuralist one (Michel Foucault, Jacques Derrida), Ludwig Wittgenstein's later works, and Clifford Geertz's anthropology have also played a considerable role. Among other significant influences are the Frankfurt School (Walter Benjamin, Theodor

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32111-0

Adorno, Max Horkheimer, and Herbert Marcuse) and symbolic interactionism.

The Tenets of Postmodernism

There are two main tenets, mirroring the distinction between postmodernism and postmodernity: while the latter designates the social and cultural features of late capitalism, distinguishing them from earlier phases (modernity), the former designates a theoretical and methodological program, as distinct from earlier (modernist) ones.

The Analysis of Postmodernity

The analysis of postmodernity developed at the beginning of the 1970s, continuing a preoccupation already found in the works of Georg Simmel, Thorstein Veblen, and the Frankfurt School. Postmodernity is a late phase in the evolution of the capitalist system, seen either as a continuation and intensification of modernity, or as a substantially new stage. It is characterized by the transition from manufacture to a decentralized services economy; science and complex technological systems play a key role here. Decentralization, together with the pervasiveness of expert and technological systems in all domains of everyday life, leads to a fragmentation and diversification of social identities. The electronic media (television, computers, video) are prominent in the constitution and presentation of social reality; visual and linguistic symbols become pervasive, while popular cultural forms diversify and expand. Society is therefore fragmented and heterogeneous; social order is always local and contextual, and works as an assemblage of symbolic codes. Production and consumption, social stratification, as well as personal and collective identities become dependent on such codes. They are understood as a support, a medium for, and an outcome of social action. This notion becomes a general explanatory paradigm: every domain of societal organization can be seen as a symbolic system and analyzed accordingly.

The emergence, spread, and popularity of electronic media, particularly of socialization platforms and of multi-user games, are accompanied by forms of social interaction and activities that do not entirely overlap in their structure with the face-to-face interactions prevalent in everyday life (Boellstorff, 2008).

Consequently, sociology (an outcome of modernity itself) should take fragmentation, decentralization, relativization, and the mediated character of social reality into account; it should adapt its own tenets and claims as well as its own modes of analysis and representation to these changes. Starting from these premises, Zygmunt Bauman (1992) has argued that notions like sociality, habitat, self-constitution, and body are better suited for the analysis of contemporary social processes than the traditional concepts of society and order. The increasingly dominant focus on virtual worlds' or 'digital cultures' (Miller, 2011) has been accompanied by claims that fragmentation, disconnectedness of the parts, and to some extent disembodiment (or dematerialization, meaning the dominance of symbols over the material features of social life) characterize social reality.

The Critique of Modernist Sociology

During the 1980s, a second theme made its way from philosophy and literary theory into sociological debates. It was a critique of the status of sociological theory as a modernist product, and it drafted a new methodological program. This debate raised a series of questions about the validity claims of scientific theories, the nature of scientific truth, and the status of the knowing subject, arguing that (1) all knowledge is contextual and local; (2) the validity claims of any scientific theory are not to be found in some abstract, universal criteria, but are rather the results of either negotiated consensus or power struggles; and (3) as a consequence, the knowing subject does not dispose of universal criteria to ascertain the validity and truth of his or her knowledge. The subject should not be seen as autonomous with respect to an objective, given world, but rather as the product of social circumstances. Since knowledge has a contextual and local character, scientific theories are reinterpreted according to local conditions: they are open-ended and cannot be controlled by their authors. Scientific theories are not determined by external validity and truth criteria; they work as systems of symbols enabling certain courses of social action and promoting a certain worldview. On these grounds, there should be a structural similarity between texts and social order: both are locally determined, network-like, open-ended systems of symbols requiring certain kinds of action from the actors embedded in them.

Notions like text and performance should occupy a prominent place in the analysis of social phenomena. Sociology should focus on investigating and describing how symbol systems work in particular social contexts, instead of producing all-encompassing theories. A corollary of these arguments is that sociological theories should acknowledge the fragmentation and diversity inherent in the local character of knowledge; they should explore their consequences for the world we live in, and should experiment with new modes of representation – like poetry, or dialogical forms. These epistemological claims overlap with those of the first strand of postmodernist sociology. However, while the first strand derives the fragmentation, relativization, and diversification of knowledge from social changes, the second one takes them as stemming out of a number of epistemological, universally valid first principles.

At the end of the 1980s and in the early 1990s, such metatheoretical topics were intensely debated in sociology and, for a short time, even eclipsed the first strand of postmodernism. However, the acceleration of globalization processes and the advent of new communication technologies has brought social analysis to the forefront again.

The Methodology of Postmodernist Sociology

One important methodological aspect is the antipositivist and antiverificationist stance: there is no totalizing explanatory model and no universally valid verification procedure. Postmodernist sociology stresses the role of qualitative methods in the analysis of contemporary social phenomena, as a consequence of the prominence of visual and linguistic symbols. While some authors (Richardson, 1997) emphasize interpretation and subjectivity, others (Lemert, 1997) argue that methodology

must preserve objectivity and logical consistency. There has been an increased sociological interest in discourse analysis, understood as a cluster of techniques for grasping the emergence, functioning, and context-boundedness of symbolic codes. More recently, discourse analysis has been complemented by a heightened interest in the analysis of visual assemblages such as the imagery of video games or of Internet videos. The prominence and sometimes prevalence of images over text in electronic communication formats have been accompanied not only by the growth of visual studies (Elkins, 2003), but also by a marked interest for visual modes of sociological expression, such as film. The emphasis placed on modes of expression includes writing processes and images as sources of conceptual enrichment in sociology. Poetry, drama, or film is promoted as a legitimate complement to the established, academic expository modes. Hybrid forms of sociological expression have appeared too – for example, in works combining academically written texts, poetry, and artwork (Haraway, 1997).

Fields of Postmodernist Research

Postmodernist analyses have been prominent in domains like work and organizations, political action, science and technology, commodification and consumption, gender, media, and popular culture. George Ritzer (1993), for example, examined the new forms of work that emerge in the knowledge-based, global economy: they are characterized by fragmentation, local specialization, flexibility, and mobility, on the one hand, and by global dispersion and typification, on the other. Under these circumstances, the temporal and spatial conditions of work change substantially: while the lifespan of products shortens, they need to be replaced faster, and worktime expands. Tensions arise between requirements for flexibility and mobility, on the one hand, and typification, on the other. New directions in commodification and consumption complete this picture. Commodification is understood as the relentless expansion of market exchange, which reshapes social relationships according to its own logic; the pendant of this process is the increased social significance of the act of consumption. Jean Baudrillard (1972), for example, has argued that symbolic consumption becomes one of the main social mechanisms through which individual and collective identities, as well as social relationships are defined and reproduced.

In political sociology, the analysis has focused on political discourses and symbolisms, and on the spectacular form taken by political events. Another direction has been to examine the strains put on democracy by the media-induced forms of political action, and by the globalized economy. Authors like Chantal Mouffe (1992) have asked whether the new economic and political conditions do not require devising new forms of democratic participation and of political action.

With knowledge lying at the core of the postmodern society, science has been a domain of sustained investigation. The focus has been on the changes brought about by the new information and biomedical technologies in social life, as well as on the role and effects of complex technological systems. Bruno Latour (1991) and Donna Haraway (1997), among others, have argued that such systems are so pervasive and deep-reaching and that social life is dependent on them to such an extent that new forms of social symbiosis have emerged; these are described with the help of notions like the cyborg society, hybrids, or networks of human and nonhuman actors. These authors have called for a revision of the conceptual apparatus of sociology on the grounds of the relationships between human actors and technical systems.

A further domain of investigation, situated at the crossroads between feminist and postmodernist sociology, has been that of gender and sexuality. Postmodern diversification brings forth a fragmentation and multiplicity of gender and sexual identities. The distinctions between genders become blurred; some forms of sexual identity formerly considered marginal gain a new significance, and new sexual identities emerge (e.g., transsexuality). Owing to the local and contextual character of knowledge, the gender specificity of knowledge and experience has to be taken into account. Several authors (e.g., Smith, 1990) have explored the ways and the implications of gender-specific knowledge in the workplace, the field of politics, popular culture, and the public sphere.

One of the key domains in which the impact of postmodernist sociology has been felt is that of the electronic media and communication. The popularity of Internet socialization platforms, and also of multiuser games and instant messaging, has brought to the fore the issue of identity formation in various interaction formats (Castronova, 2005). Online identities can be tied to features different from those of everyday life identities; they can be less stable and more prone to variability. Online communication structures (such as the allocation of speaking rights) are different from their offline counterparts. This has raised the issue whether virtual worlds change the ethical underpinnings of social interactions. Finally, postmodernist sociology has also considerably influenced the subfields of cultural and urban studies, reinvigorating a research tradition that goes back at least to the Chicago School of sociology.

The State of Postmodernist Research

Postmodernist sociology has been around for approximately four decades; while controversial and contested for some of the more radical theoretical stances, many postmodernist ideas have made inroads into mainstream sociology. At the same time, it has continued and enriched a series of themes already present in classical sociology – like the sociology of consumption or the study of popular cultures. It has also pioneered some new domains of research, such as the study of Internet cultures, of the media, or (together with ethnomethodology) that of the impact of computers. Together with feminist sociology, it has had a considerable influence on the sociology of gender and sexuality. Its empirical, domain-oriented impact has been more significant than that of its pure theoretical tenets.

New Research Directions

The cultural forms induced by the electronic media (e.g., the culture of software programmers, of Internet users) have been a major focus of study since the 2000s. The changes in consumption patterns and market relationships brought about

by the Internet, the rapid expansion of online communications, or the Internet's role in the globalization processes have taken center stage in empirical investigations. As electronic media continue to expand and diversify in often surprising ways, they will also continue to provide a major challenge to postmodernist research.

Abstract

Postmodernism is considered here to be a methodology. However, because postmodern social science is based on intuition, emotion, faith, subjective judgment, imagination, and introspection as methods, several methodologies exist. Accordingly, this article describes postmodern methodology in opposition to quantitative and qualitative methods and, in general, to any method seeking truth and generality in any way. It emphasizes interpretation as introspective, intersubjective, and antiobjectivist.

If methodology is defined as referring to the foundations of knowledge, as how we perceive and understand reality, as well as how we study it, then there is not only a single implicit postmodern methodology. There are several. But all challenge the methodological assumptions associated with rigorous, modern social science inquiry, be it qualitative or quantitative (Dickens and Fontana, 1994). Some postmodernists look to deconstruction as a method. Others employ introspective, intersubjective, and antiobjectivist interpretation. Still others look to wisdom, lived experience, storytelling, empathy, introspection, imagination, subjective judgment, and faith, as method. A few reject methodology altogether, constructing an intellectual framework within which there is no need to bother about it.

Indeed, there are serious philosophical differences between postmodernism and the enlightenment norms of traditional science. Some postmodernists are uninterested in generalization, definitive explanation, replication, validity, reliability, etc. Neither prediction nor theory building is a major concern. They look to deconstruction as method. Deconstruction tears a text apart, revealing its contradictions and assumptions. Other postmodernists criticize modern methodology and seek to revise it, to build upon it. They look for alternatives to what they call the old, past, closed conventional social science methods inherited from the natural sciences. But they do so without entirely rejecting reason, consistency, and coherence of argument. Although they abandon foundations, they retain what they call preferences.

Many postmodernists see the need for new standards for evaluating knowledge. Their criteria are likely to be subjective in nature, including, for example, flexibility, sensitivity, and interactivity. They look for beauty, strength, or force in a text. Some value elegance of expression and style, and seductiveness of content while others say that such criteria are community specific and so cannot be enumerated. Still other postmodernists willingly employ more direct valuations, such as negation of oppression, exploitation, and domination, or the affirmation of liberation, freedom, insubordination, and resistance as key standards (Rosenau, 1992).

A Postmodern Methodological Focus

Postmodern methodology focuses on the margins and postmodern social scientists highlight the unique and the unusual. They concentrate on the enigmatic and appreciate the unrepeatable. They seek to multiply paradox, to invent ever more elaborate repertoires of questions as much as to determine answers. They look to 'différance' (Derrida, 1972) rather than sameness, regularity, and synthesis. 'Différance' is a structuring principle that tells us that definition rests not on some inherent characteristics of a thing but rather in terms of its negative and positive references to other texts. It also suggests that in the end, definition is never final, always postponed, deferred forever (Derrida, 1981).

Postmodern methodology seems driven by substantive concerns quite different from those modern social scientists focus upon (Cullenberg et al., 2001). Postmodernists direct their attention to everyday life and they gravitate toward mini-narratives or stories. Postmodern social science is a 'systematic commentary on the knowledge of daily life' (Bauman, 1990). This means examining what is assumed to be quite ordinary and attributing a new importance to it. Postmodern social science makes room for the unexpected, the mystical, and the metaphysical. Concepts such as fate and spirituality are, once again, legitimate (Griffin, 1988).

Linking Substance and Method

If there is a close association of substance and method, then conventional social science methods are not helpful given the postmodern focus on the margins, the unexpected, the paradoxical, and the unrepeatable. Empirical methods require repeatability so that careful measurement can be carried out and statistical norms met. But the subject matter of interest to postmodernists does not recur necessarily and its very interest may be in the fact that it is transient, constantly in flux, and difficult to capture. Because of their substantive foci, these postmodernists require methods that are open and flexible, rather than highly structured, codified, and technically detailed. They must be adaptable to a great variety of situations because of the range of potential application. There is no easy methodological recipe for doing this type of research.

Going Beyond Qualitative Methods

Postmodernists would reject any argument that their methodology is simply qualitative social science in a different guise.

The gamut of modern qualitative approaches developed over the years (from observation to participant observation) retains a preoccupation with generalization and replication as much as an appreciation of complexity. Those employing conventional qualitative methods in social science have invested enormous energy in separating out what is procedurally acceptable from the unqualified. All this is abandoned in the postmodern methodology that embodies an attitude of humility and respect. It does not try to convince others that its own methodological perspective is right, superior, truthful, objective, the best assessment, or the source of the only correct answer. It does not settle on solutions or give privileged voice to any particular, singular point of view. It does not attribute authority to authorship. It queries and interrogates constantly. It follows its own advice: no new metanarrative. A metanarrative is a global worldview, a 'mastercode' that assumes the validity of its own truth claims.

An Upbeat Postmodern Methodology

What methodological alternatives does postmodernism have to offer vis-à-vis modern social science methodology? It emphasizes personal wisdom, lived experience, and knowledge as rich sources of material that inform writing and research. We are counseled to look to music, art, poetry, and literature instead of census data and public opinion polls. A postmodern social scientist would have more confidence in feelings, faith, empathy, emotion, insight, sensitivity, intuition, imagination, subjective judgment, and introspection as method. Postmodern social scientists are obviously and openly more comfortable with these than with an exclusive confidence in reason and logic. But by praxis, if not discourse, some postmodernists communicate that their alternative methodologies are of most value if disciplined by reason and logic. This amounts to coming to terms with the best of the Enlightenment heritage but without being intimidated by it. It suggests a refusal to accept the authority of modern science but also a desire to salvage from it whatever is of interest, such as the possibility of an interactive and reciprocal relationship between, say, reliable knowledge and meaningful participation in the public sphere, the creation of social life and political action, the enhancement of personal development, self-expression, self-determination, and collective praxis (Jennings and Graham, 1996). Doing social science might also have to be fun, enjoyable, entertaining rather than somber, listless, and mundane (Bakhtin, 1973; Todorov, 1984). It would not seek to demonstrate the obvious so much as to highlight the overlooked and the unrecognized.

Methodology as Art and Literature

Postmodern social science is often viewed as vision and art more than trained observation. It disperses any clear distinction between self and other; fact and values; author, text, and reader. It is inspired by the cultural and contextual preoccupations of anthropology where the distinction between literature and science was never clearly established. Anthropology had to be content with differing 'evocative devices of metaphor and imagery' because it was so difficult to arbitrate between different narratives from the past (Richardson, 1988). Postmodern social science methodology centers on 'listening to,' and 'talking with' the other (Tyler, 1986). The reader 'writes' the postmodern text and in so doing postmodern social science gives voice to those previously silent. It empowers through the methods of interpretation and criticism.

Postmodern methodology employs a literary capacity and it reinvigorates the mininarrative as a story that is worthy of notice even if it is not necessarily true in the modern sense of science. Storytelling is both a method and a means to emancipatory power (Newman and Holzman, 1999). The need to reconcile various stories, narratives, or research findings may or may not be urgent. The postmodernism tolerance for diversity and its indulgence of discrepancy reflect the fact that there is no rush to create, to construct, to accumulate, and to impose new knowledge in the modern sense.

Methodology as Interpretation

Postmodern methodology is interpretive but postmodern interpretation bears but slight resemblance to the more conventional social science forms of interpretation (Alvesson and Sköldberg, 2009). Modern social science understands interpretation to be the careful consideration of data with the goal of locating patterns. Meaning is not arbitrary and some interpretations are assumed to be better than others. But neither does postmodernism resemble hermeneutic interpretation that is more subjective and less ambitious than modern social science's interpretation. Hermeneutic interpretation, unlike postmodern interpretation, seeks to probe the 'silences,' to uncover a deeper meaning, masked, and hidden perhaps, but waiting to be discovered (Dreyfus and Rabinow, 1983; Madison, 1988). There is a current within postmodernism that says there simply is no 'meaning' to uncover. In many ways hermeneutic interpretation accepts truth, universality, and a shared discourse (a community of understanding).

Postmodern interpretation is *introspective*, *intersubjective*, and *antiobjectivist*, a form of individualized understanding. Postmodern theories of interpretation no longer 'ground,' they rather 'mediate' (Kugler, 1988). They range from 'interpretative reason' (Bauman, 1990) to prayer and chanting as 'interpretative communication.'

Methodology for a Complex Intertextual World

Postmodernists see the world as so complex that any direct causal statements relating to reality would necessarily be simplistic. They argue that it is impossible to established temporal priority in a simple fashion. They similarly are suspicious of modern versions of time that clearly delineate the past from the present, and include a strict version of linear time or geography. Their preference is for a present-oriented social science that erases linear time and ignores strictly bounded forms of geography. Their analysis emphasizes postmodern intertextuality, including, for example, chaos theory with its view of nonlinear social dynamics, and a definitely more complex version of reality (Young, 1992).

If the social universe for these postmodernists is intertextual, this has an impact on their methodology. Relationships, interconnections, and interactions are areas of substantial

interest. Conventional research tools are hardly appropriate. Quantitative methods isolate and simplify what is being studied, holding as many extraneous variables as possible constant so as to tease out causal, predictive associations. These postmodernists seek methodologies that integrate what is being studied with all that is related to it even if this complicates the research task, because in the end explanation in any absolute sense may be impossible.

Relativism and Questioning Postmodernists

Postmodernism is plagued, because of its European philosophical precursors, with the charge of relativism (Gellner, 1992) but many postmodernists defy this heritage and reject relativism. This is especially true for the postmodernists who come from a philosophically committed heritage: marxism, feminism, environmentalism, peace movements, ecology groups, and religious studies (Griffin, 1988, 1990; Kumar, 1995; Leonard, 1997). This leads them to argue that while deconstruction is an interesting first step to a postmodern methodology, it is limited because its goal is to undo all constructions. Deconstruction's intent is not to improve, revise, or offer a better version of the text, so they reject it. Postmodernism, in this view, must ultimately move to reconstruction and by extension, methodology remains essential.

Methodology Defined Narrowly

If methodology is defined narrowly as the rules and regulations of inquiry, then postmodernists must question the whole undertaking, arguing that there is no such thing as a postmodern methodology. 'Rules,' as such, are modern, not postmodern in character because they imply hierarchy, a series of good–bad evaluative criteria, an assessment on the basis of a set of agreed upon standards. Postmodernists reject rule-bound approaches as 'metanarratives.' Critics of postmodernism, however, respond that the absence of rules is itself a rule, the rule that 'anything goes' (Feyerabend, 1975; Heller, 1987) and that there is, thus, a postmodern methodology.

Rejecting Methodology Altogether

Postmodernists, inspired by Heidegger and Nietzsche, are antiscience and anti-Enlightenment, and this leads to an absolute relativism and to methodological nihilism. This postmodern orientation emphasizes the hopelessness and meaninglessness of life; theirs is the pessimistic, dark side of postmodernism (Rosenau, 1992).

Some such postmodernists practice epistemological impossibilism. They do not intend to provide 'clear reasoned defense.' They tell us their texts offer 'no consistent argument' and that 'not all points made are "necessary."' They boast that by design 'some essential matters are forgotten' (Corlett, 1989). To insist that these postmodernists develop a self-conscious methodology is to 'do violence' to their views, to impose one's own perspective, and thus diminish them by forcing them to acknowledge your views (Ashley and Walker, 1990a,b; Lyotard, 1988). In the end, from this postmodernist methodological perspective, we can never really know anything, not even our own feelings and emotions. These postmodernists speak of the death of the author (as agent) and of the absence of the subject (as a real person) with a specific identify. This means that they escape agency, accountability, and responsibility. They deny causality, question efforts to represent reality (through social science theory), and they contend that all interpretations are equally interesting (Miller, 1981).

All textual meaning, all interpretation, is undecidable within this postmodern perspective, because there is no final sense of a text and everything is a text in this postmodern world. No interpretation can be regarded as superior to any other (Latour, 1988). There is a multiplicity of readings and these postmodernists refuse to privilege one statement over another. "Every understanding is a misunderstanding" (Culler, 1982; Norris, 1988). Within this intellectual framework there is no need to bother about methodology at all.

Conclusion

Postmodern methodologies will be judged in the long term by their product. In the arts and literature, postmodern methods can be fascinating, challenging, and interesting. They stimulate creativity and innovation as exemplified by the writings of Umberto Eco, Italo Calvino, Milorad Pavic, and Salman Rushdie. They dissolve the boundary between fiction and social critique as the works of Jean Baudrillard and Michel Foucault so well illustrate. The fruitfulness of postmodern methodologies in the applied social sciences is yet to be demonstrated. Many feel them to be seriously flawed and epistemologically dubious. Postmodern methods contributed little toward the solution of the greatest social problems of the twentieth century. But then, that is not what they set out to do; it was never the intent.

Postmodernism: Philosophical Aspects

Paul Patton, University of New South Wales, Sydney, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Postmodernism is an unstable concept because of the complex ways in which it overlaps with other concepts such as postmodernity, poststructuralism, and pragmatism. It may be identified by reference to an open-ended list of themes, including a preference for plurality, difference, and identity over unity, universality, and identity. Postmodernism also privileges a nonreferential conception of signs and images as simulacra rather than representations, although no less real in their effects. It also seeks to account for the possibility of criticism and to maintain commitments to freedom and progress, however redefined.

'Postmodernism' is a term that defies simple definition. Although earlier uses are recorded, the term has been widely used since the 1960s to refer to a range of antimodernist attitudes and strategies in art, architecture, and literature. References to postmodernism in philosophy and social theory first appeared in work by Jean-François Lyotard and Richard Rorty during the early 1980s. Philosophical postmodernism became associated with the idea that there was a 'crisis' in representation, with the abandonment of belief in a universal subject of reason and value, and with the rejection of unitary schemas of progress inherited from the Enlightenment. In place of these foundational motifs of modern thought, postmodernism emphasized difference, diversity, irreducible conflict, and the absence of progress in human affairs.

Bertens' *The Idea of the Postmodern: A history* begins with illustrations of the sometimes contradictory ways in which the term has been employed. For example, by 1970, modern painting had long abandoned the idea that representation or narrative was essential to its art. In explicit reaction against modernism understood as the self-reflexive exploration of the formal possibilities of painting, postmodern painting involved a reprise of representation and narrative. In a similar fashion, postmodern architecture rejected the formalism of the postwar International style and reembraced historical and vernacular styles. By contrast, at least in some of its manifestations, literary postmodernism involved a move in the opposite direction away from narrative and representation toward a form of radical self-reflexivity. Bertens concludes that, depending on the artistic discipline, "postmodernism is either a radicalization of the self-reflexive moment within modernism, a turning away from narrative and representation, or an explicit return to narrative and representation. And sometimes it is both" (Bertens, 1995: p. 5).

There are several reasons why postmodernism should be "a particularly unstable concept" (Bertens, 1995: p. 12). First, to the extent that postmodernism is considered to be a cultural movement alongside others such as romanticism, positivism, or structuralism, then like these it will encompass a variety of distinct aesthetic and intellectual strategies. Second, commentators and users of the term hesitate over whether postmodernism is primarily a temporal or a typological concept. The prefix and the manner in which the term has been employed in the arts suggest a temporal reference, even though estimates of the beginning of the postmodern era range from the 1860s to 1980s. By contrast, some theorists consider postmodernism in the arts and culture to be a radicalization of tendencies already present in the modern. For example, Lyotard argues that postmodernism in painting stands for an aesthetic of the sublime that embraces the ever-renewed attempt to 'present the unpresentable' (Lyotard, 1983). Following this line of thought, Umberto Eco suggests that postmodernism should not be chronologically defined but rather treated as "an ideal category – or better still, a *Kuntswollen*, a way of operating. We could say that every period has its own postmodernism, just as every period would have its own mannerism" (Eco, 1985: p. 66). Third, the concept of postmodernism stands in a variety of complex relations to other concepts such as modernity, postmodernity, modernism, poststructuralism, and deconstructionism. Since the meaning of these concepts is similarly uncertain, so our understanding of 'postmodernism' will be affected by the particular meaning attached to these related concepts. In view of the many different phenomena to which it has been applied, it is common for discussions of postmodernism, to begin, as this one has, with the claim that the term has no clear meaning (Eco, 1985: p. 65; Rorty, 1999: p. 262).

Modernity/Modernism

Just as modernism is often regarded as a response to the process of modernization that transformed the material conditions of European society during the nineteenth century, so postmodernism is often presented as a consequence of the restructuring of late capitalism at the end of the twentieth century. The historical period of European modernization, which extended from the middle of the eighteenth through to the middle of the twentieth century, saw the development of industrial infrastructure and means of production such as railways, automobiles, air transport, electricity, and telegraphic and telephonic communication. It also saw the growth of cities, the spread of public schools, hospitals, and prisons, and the development of bureaucratic and rational procedures for the government of social life. 'Modernism' commonly refers to an artistic sensibility that embraced innovation and change. In its early stages, modernism involved a positive sense of living at the dawn of a new era. To be modern implied a heroic

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63062-3

commitment to action and to revolutionizing oneself as well as the means of artistic production. In its later stages at the end of the nineteenth century and the beginning of the twentieth, modernism involved experimentation with the style and form of the various arts, hence the dynamic of successive avant-gardes in literature, music, and visual arts.

Theorists of postmodernity such as Fredric Jameson and David Harvey assert a parallel connection between the changes associated with the restructuring and globalization of late capitalism and the emergence of a postmodern culture (Jameson, 1991; Harvey, 1989). They argue that changes in technology, urban space, and forms of consumption have created the conditions of a new mode of experience of self and others. In particular, the 'compression' of social space and time brought about by new electronic and communications technologies is reflected in a new cultural sensibility. Just as the destruction of traditional ways of life and thought wrought by modernization was often linked to a tragic sense of loss, so theorists of postmodernity argue that a similar kind of homelessness is generated by the late twentieth century mutations in our experience of space and time. Among those who take a negative view of the cultural experience of postmodernity, Jameson argues that it does not sustain a sufficiently robust sense of self and history. He suggests that the rapid evolution of postmodern urban space has overtaken "the capacities of the individual human body to locate itself, to organize its immediate surroundings perceptually, and cognitively to map its position in a mappable external world" (Jameson, 1991: p. 83). On his account, postmodernity is experienced as incapacity in the face of complex and discontinuous social spaces and as disorientation in the absence of a rich sense of the past or future. The result is a widely documented fragmentary and schizophrenic experience of subjectivity, along with a tendency toward affectless repetition or 'blank parody' of past forms of artistic and cultural production.

For others, modernist and postmodernist alike, the appropriate affective response to change is less a matter of nostalgia for older ways of being at home and more a question of orientation toward the future. This was the attitude of Friedrich Nietzsche, who in the view of many, is the source of much postmodern philosophy. For Gianni Vattimo, for example, "It could legitimately be argued that philosophical postmodernity is born with Nietzsche's work" (Vattimo, 1991: p. 164). Writing at the end of the nineteenth century in response to what he took to be the defining event of modernity, namely the fact that belief in the Christian God had become unsustainable, Nietzsche employed the condition of 'homelessness' as a metaphor for the situation of those who no longer believe in a divine providence but nevertheless look forward to 'the strengthening and enhancement of the human type.' Among the Europeans of his time, he wrote, there is no shortage of those "who have a right to call themselves homeless in a distinctive and honorable sense … "We children of the future – how *could* we be at home in this today?" (Nietzsche, 2001: p. 241).

Unity and Plurality

A feature of many cultural responses to the transient, fleeting, and ephemeral character of modern life is their attachment to ideas of unity, whether in the object to be represented or the artifact to be produced. Thus, for example, modernists believed that a machine or a city could be a unified, smoothly functional object, and a novel or work of art could be a complete, self-contained, meaningful entity. Even where there is experimentation with diverse modes of representation, this is undertaken in the attempt to convey a single complex and multifaceted reality. And even where there is a dizzying succession of conceptions of the nature of a particular art such as painting, there is, nevertheless, a conviction at each stage that at last the true form of the art has been discovered.

Even though 'modernism' does not have the same currency as a classificatory term in philosophy and social theory as it does in the arts, there are epistemological parallels to this modernist attachment to unity. Modernist thought would be that which tolerated perspectivism only on the assumption that there is a single, intelligible reality to be presented. Even when there is an acceptance of surface incoherence, as in Marx's account of the contradictions of capitalism or Freud's account of conscious behavior, this is balanced by the discovery of an underlying structure that produces such contradictory effects. In this sense, Harvey argues that modernism "took on multiple perspectivism and relativism as its epistemology for revealing what it still took to be the true nature of a unified, though complex, underlying reality" (Harvey, 1989: p. 30). By contrast, postmodernism is associated with the acceptance of difference and plurality in both ways of being and ways of knowing. In opposition to the ideal of unified objects of knowledge, whether texts or artifacts, postmodernism refers instead to networks, open systems, or the dissemination of meaning. In opposition to the modernist ideal of unified science, postmodernism upholds the idea of irreducible difference and even incommensurability among the varieties of knowledge.

In their efforts to make positive sense of such difference, along with the experience of being estranged from the social world in which they must live, postmodernists often have recourse to the concept of irony. Umberto Eco argues that the postmodern attitude is encapsulated in the irony that acts and speaks in full awareness of the degree to which all our ways of acting and speaking involve repetition of the past: "the postmodern reply to the modern consists of recognizing that the past, since it cannot really be destroyed, because its destruction leads to silence, must be revisited, but with irony, not innocently" (Eco, 1985: p. 67). Rorty contrasts metaphysical thinkers committed to the unity of truth and a hierarchy of values with ironists who are conscious of the contingency and mutability of the 'final vocabularies' employed to make sense of their lives, yet nonetheless committed to the values that those vocabularies embody (Rorty, 1989: p. 73). He argues that, to the extent that postmodernism stands for anything distinctive in philosophy, it refers to a pluralism shared by a range of modern thinkers such as Nietzsche and William James. After having used the term 'postmodernism' in the 1980s to describe his own philosophy and that of others such as Heidegger and Derrida who were, in Lyotard's phrase, "distrustful of metanarratives" Rorty became skeptical of its utility. In the Introduction to *Essays on Heidegger and Others* (Rorty, 1991), he says that he had given up on "the attempt to find something common to Michael Grave's buildings, Pynchon's and Rushdie's novels, Ashberry's poems, various sorts of

popular music, and the writings of Heidegger and Derrida" (Rorty, 1999: p. 1). He gave up on the attempt to periodize every aspect of culture in favor of efforts to periodize particular disciplines and genres of cultural activity, suggesting that so-called postmodern philosophy is better described as post-Nietzschean and pragmatist philosophy. In a later essay, he argued that as various as the definitions of 'postmodern' are, "most of them have to do with a perceived loss of unity" (Rorty, 1999: p. 262).

Postmodernism and Poststructuralism

Postmodernism in philosophy and social theory is widely associated with the work of a number of French thinkers, notably Baudrillard, Deleuze, Derrida, Foucault, Irigaray, and Lyotard. Because these authors emerged from the shadow of the structuralism of Althusser, Lacan, Levi-Strauss, and others at the end of the 1960s and beginning of the 1970s, they are also commonly referred to as post-structuralists. By different intellectual paths, these thinkers rejected the idea that theories and concepts simply represent a preexisting reality. For some, such as Derrida or Baudrillard, this conclusion was reached via a radicalization of Saussurian theses about the arbitrariness of signs and the manner in which their sense is derived from differential relations to other signs. For others, such as Foucault, similar conclusions were reached via Kantian and Heideggerian views of the role played by language and thought in the construction of its own objects. A consequence of Foucault's historicization of the Kantian idea that objects of knowledge are determined in part by the underlying rules governing discourse is that 'truth' acquires a history and can no longer be measured solely against an independent reality.

While the work of Foucault and others does imply a form of historical relativism with regard to truth, it is overstating the case to suggest that the resultant 'crisis in representation' amounts to "a deeply felt loss of faith in our ability to represent the real, in the widest sense" (Bertens, 1995: p. 11). It is not our ability to represent reality but rather what Deleuze calls the representational "image of thought" that is impugned by poststructuralist epistemology (Deleuze, 2011: pp. 164–213). Foremost among the influential philosophical assumptions that make up the representational image of thought is the idea that thought has an 'affinity' with truth, that it seeks truth by nature and that it is fully equipped to attain a true representation of the world. For Deleuze as for Heidegger, it is not recognition or representation but creation that is the highest expression of thought: "thought only thinks when constrained or forced to do so, in the presence of what 'gives cause to think' or of what is to be thought – and what is to be thought is just as much the unthinkable as the unthought, in other words the perpetual fact that 'we do not yet think'" (Deleuze, 2011: p. 182).

The turn to language in Heidegger's later philosophy was paralleled by the linguistic turn in analytic philosophy, inspired by Wittgenstein's posthumous *Philosophical Investigations*. Both of these philosophical tendencies converge in Rorty's neo-pragmatism (Sheehan, 2004: p. 24). For Rorty, the core of postmodernism in philosophy is the abandonment of the correspondence theory of truth and the "theologicometaphysical belief that Reality and Truth are One – that there is One True Account of How Things Really Are" (Rorty, 1999: p. 262). A less negative characterization might say that postmodernism does not, so much, reject the idea that thought represents reality as embrace more complex views of what representation entails. In this manner, for example, Foucault's genealogies of modern punishment and sexuality drew attention to the ways in which what passes for truth in the social sciences is bound up with the exercise of power over individuals and populations. More generally, postmodernism has drawn attention to new aspects of social reality, such as the systems of thought and language, which condition public discourse and what we take to be the truth. It has also given rise to new kinds of analysis of cultural and social phenomena: genealogical, deconstructive, narratological, and so on. In these ways, postmodernism has given rise to new research methods and new objects of analysis in anthropology, sociology, and other social sciences, as well as in jurisprudence and the philosophy of law (Clifford and Marcus, 1986; Dickens and Fontana, 1994; Litowitz, 1997).

Universalism and Freedom

One of the most influential formulations of postmodernism in philosophy was provided in Lyotard's *The Postmodern Condition* (Lyotard, 1984), first published in 1979 (Sim, 2005: pp. 6–10). Here, Lyotard uses 'modern' to refer to any form of knowledge that seeks legitimation by appeal to some 'grand narrative, such as the dialectics of the spirit, the hermeneutics of meaning, the emancipation of the rational or working subject, or the creation of wealth.' He then defines the postmodern attitude as one of "incredulity toward metanarratives" (Lyotard, 1984: pp. xxiii–xxiv). Lyotard is not concerned with postmodernity understood as an historical epoch, since his inquiry is limited to "the condition of knowledge in the most highly developed societies" (Lyotard, 1984: p. 13). Rather, his aim is to show that the supposed transcendent status of scientific knowledge is an illusion sustained by a certain narrative language game. He argues that the privileged status of scientific knowledge is destined to disappear once it is accepted that this status depends upon a narrative that privileges science over other kinds of language game. In European philosophy, this narrative of legitimation has either followed the French Enlightenment link between the pursuit of knowledge and human emancipation, or the German Idealist construal of history as the process of the realization of reason through the sciences. Lyotard asserts not only that these 'metanarratives' have lost their appeal, but also that the very idea of transcendent legitimation has given way to forms of legitimation, which are local and immanent in particular social practices and forms of life. The postmodern condition therefore is the state in which we must accept this plurality of micronarratives and find other ways to address the resulting conflicts that do not involve the imposition of a single master narrative.

In *Modernity—An Incomplete Project*, Habermas (1983) provided an influential response to Lyotard and other post-structuralist thinkers. He characterized the philosophical project of modernity as the desire for unification of the three spheres of cultural value distinguished by Kant – the

theoretical, the practical, and the aesthetic – and for the application of the results of these distinct kinds of judgment to the improvement of everyday life. According to this view, the project of modernity consisted in the effort of Enlightenment thinkers "to develop objective science, universal morality and law, and autonomous art, according to their inner logic. At the same time, this project intended to release the cognitive potentials of each of these domains from their esoteric forms. The Enlightenment philosophers wanted to utilize this accumulation of specialized culture for the enrichment of everyday life – that is to say for the rational organization of everyday social life" (Habermas, 1983: p. 9). The major obstacle preventing the realization of this project, according to Habermas, lay in the manner in which these spheres have become separated from one another, both institutionally and in their internal logics and forms of argumentation, and in the manner in which they have become increasingly separated from a lifeworld dominated by instrumental rationality.

Habermas's solution to this problem appealed to the procedural rationality implicit in language use, or what he calls 'communicative reason,' as a means to restoring the possibility of intersubjective consensus. Both his diagnosis and his solution to the problem of modernity are founded upon the Enlightenment belief that universal standards of judgment are necessary, both for the development of reason and for moral progress. By contrast, postmodern thinkers reject the idea of progress in human affairs in favor of the idea that there are many ways in which the present differs from the past. In common with Lyotard, they reject the idea of universal standards of judgment, value or 'legitimation.' Although Habermas characterizes French thinkers such as Foucault, Derrida, and Lyotard as "young conservatives" (Habermas, 1983: p. 14), most of them do not wish to abandon the ideals of freedom and emancipation but only the approach that links these to universality, unity, and consensus and does so in the name of the Enlightenment.

In response to Habermas's criticisms, Foucault presented his practice of genealogy as serving the cause of freedom, while suggesting that it represented a critical ethos or attitude toward the present that had always belonged to the Enlightenment (Foucault, 1984). Genealogical criticism does not seek to identify the universal structures of human knowledge and moral action, but rather takes the form of an historical investigation into the means by which we have been constructed as certain kinds of subject. Against the presumption that human reason is an unchanging and undivided faculty, Foucault views reason as divided among the distinct rationalities embodied in particular systems of thought and practice such as 'medicine,' 'discipline,' or 'sexuality.' The aim of this type of historical investigation, Foucault suggests, is to determine "in what is given to us as universal, necessary, obligatory, what place is occupied by whatever is singular, contingent, and the product of arbitrary constraints" (Foucault, 1984: p. 45). Thus, in contrast to the idea that progress in human freedom depends upon the extension of the sphere in which universal rationality governs social life, Foucault presents progress in human freedom in negative terms as the escape from particular forms of domination. For many poststructuralist theorists, freedom is not linked to the achievement of universal standards of value or to the hope that dissensus will eventually give way to consensus. Rather, it is dissensus and the experience of irreducible difference that are the conditions of freedom and creativity or change in human affairs.

Difference and Multiplicity

In his later work, Lyotard introduced the concept of the differend in order to characterize the postmodern condition with respect to political and moral judgment. A differend is a conflict between parties who inhabit different regimes of utterance or discourse, the sentences of which are incommensurable with one another (Sim, 2005: p. 9). As a result, the conflict between the parties cannot be resolved peacefully for lack of a rule of judgment common to both (Lyotard, 1988: p. 9). In practice, one party tends to enforce its discursive regime on the other. Foucault also embraced the idea of radical difference between regimes of discourse. He described his critical attitude toward the present as one that endorsed differentiation from the past rather than movement toward some future identity (Foucault, 1984). However, the recent origins of this concern with difference must be sought in the philosophical work of Deleuze and Derrida published during the 1960s. Both sought to elaborate a nondialectical concept of difference, which would see it neither as the simple contrary of identity, nor as 'dialectically' identical with identity (Descombes, 1980: p. 136). Hegel was a focus of their criticism because he represented the culmination of a metaphysical tradition that treated identity as primary and difference as the derivative or secondary term. In *Difference and Repetition*, Deleuze (2011) explicitly rejects the link which Hegel forged between difference and contradiction, arguing that contradiction is not the condition or ground of difference. On the contrary, 'It is not difference which presupposes opposition but opposition which presupposes difference, and far from resolving difference by tracing it back to a foundation, opposition betrays and distorts it' (Deleuze, 2011: p. 62). Limitation or opposition is a distortion of difference, according to Deleuze, because difference in itself implies 'a swarm of differences, a pluralism of free, wild, or untamed differences' (Deleuze, 2011: p. 61). Similarly, in *Of Grammatology*, Derrida (1976) drew upon Heidegger's concept of the ontological difference between being and beings and Saussure's concept of the differentiation that gives rise to units of signification in a sign system to draw attention to the movement of deferral and differentiation (*différance*) that underlies all production of meaning (Derrida, 1976: pp. 56–65).

Both Deleuze and Derrida were concerned with the problem of how to conceive of the identity of objects such as meanings, texts, or signs that are subject to continuous variation. They sought to describe a form of unity that is not identical with itself. To this end, Derrida relied upon a series of concepts such as *différance*, the trace, and iterability, while Deleuze relied upon a concept of open or variable multiplicity derived from Bergson. In *A Thousand Plateaus* (Deleuze and Guattari, 1987), this concept of multiplicity provided the formal structure for the elaboration of a series of philosophical concepts of such things as desire, subjectivity, language use, knowledge, and forms of social organization. The concept of multiplicity, he and Guattari suggest, 'was created precisely in order to escape the abstract

opposition between the multiple and the one, to escape dialectics, to succeed in conceiving the multiple in the pure state, to cease treating it as a numerical fragment of a lost Unity or Totality or as the organic element of a Unity or Totality yet to come, and instead distinguish between different types of multiplicity' (Deleuze and Guattari, 1987: p. 32). Deleuze and Guattari defended this invention of novel concepts as a new practice of philosophy, the ultimate aim of which was to bring about new ways of speaking and acting, to enable us to perceive the world differently and thereby to bring about new worlds and new peoples (Patton, 2010).

A distinction is often drawn between 'postmodern' theorists, such as Deleuze–Guattari, Derrida, and Foucault, and theorists of postmodernity such as Jameson and Harvey. The theorists of postmodernity tend to adopt a broadly Marxist approach to society and culture, and to the cultural phenomena they see as representative of the social totality, in order to pass judgment. Their 'modernist' social theory presupposes that a total picture is possible and that cultural phenomena can be understood as effects of a certain economic 'logic.' They proceed on the assumption that critical distance is possible and that an appropriate interpretative framework will provide such distance. By contrast, the 'postmodern' theorists tend to abandon economic or other forms of historical determinism, along with the idea that a totalizing theory of society and history is possible or desirable, in favor of the idea of multiple, overlapping, and divergent histories written from the distinctive perspective of particular social groups, peoples, or interpretative frameworks (power, desire, the body, etc.). This distinction is not absolute, since there are those such as Baudrillard, Foucault, and Lyotard who might be included in both camps although at different stages of their careers. However, it is characteristic of postmodern theorists that their work involves a self-conscious attempt to theorize in a different manner, while also searching for critical strategies that do not rely upon a normative standpoint outside or apart from the object of criticism.

Simulacra and Simulation

Philosophies that seek to make difference, an object of affirmation, must do more than reverse the traditional hierarchy between identity and difference. The mere inversion of hierarchy does not change the fundamental relation between the elements involved, nor does it change the nature of those elements. For this reason, Derrida's practice of deconstructive philosophy always envisaged a further stage after the initial hierarchy has been overturned, which would involve "the irruptive emergence of a new 'concept,' a concept that can no longer be, and never could be, included in the previous regime" (Derrida, 1981: p. 42). In the course of his essays, he produced or drew attention to a series of such paradoxical concepts, including the trace, writing-in-general, metaphoricity, and Plato's *pharmakon*, all of which served to disrupt conceptual oppositions and hierarchies in philosophy. Similarly in *Plato and The Simulacrum* (Deleuze, 1990: pp. 253–266), Deleuze argued that the concept of simulacra served to undermine or 'overturn' the primacy of identity as this was embodied in Plato's conception of a model or form of which reality is only an imperfect copy.

However, it was the sociologist Jean Baudrillard who took up the concept of simulacra and applied it to aspects of everyday life. In his earlier work, Baudrillard had argued that industrial society at the end of twentieth century had entered a new phase in which consumption rather than production served to structure social relations. He argued that the Marxian view of commodities as useful items, produced in order to realize exchange value, must be replaced by a semiotically informed view of commodities as signs, produced in order to realize their 'sign value' as differential elements of a social code of signification. In a series of essays published during the early 1980s, Baudrillard built upon this analysis and other accounts of the power of mass media to argue that society had entered a new era in which simulation had replaced representation as the dominant principle of signification. The essays translated in *Simulations* (Baudrillard, 1983) combined a Nietzschean-inspired critique of metaphysics with a descriptive account of the present stage of social life as a regime of simulacra in which the distinction between reality and the forms of its representation has broken down. According to Baudrillard, there are many areas of social life, such as the media, where signs or other representations do not faithfully represent a prior reality but function in its stead. As a result, for practical purposes we live in a hyperreal social world of representations without referents, images without originals. The proliferation of media transmitted information and the speed with which it circulates creates a perpetual cultural present in which contemporary society has begun to lose its capacity to retain its own past.

Criticism without Foundations

While critics object to the nihilistic, impressionistic, and highly selective nature of Baudrillard's descriptions, his analyses of technological, media, and political events as simulations served to draw attention to this pathological feature of the experience of social reality at the end of the twentieth century. His essays have been criticized for their failure to provide any stable foundation for criticism (Norris, 1992). However, Baudrillard openly acknowledges their ironic and hyperbolic style, describing them as 'theory–fictions' intended to provoke and to challenge contemporary common sense rather than convince by evidence or argumentation. Such a provocative function is often invoked in defense of postmodern theory. At best, it is argued, postmodern approaches serve to problematize established concepts and to draw attention to ways in which traditional universalist and humanist assumptions function to exclude or marginalize differences.

Postmodern theory is also criticized for its limited and negative approach to normative issues. Critics assert that the antiuniversalism of Foucault, Lyotard, and others is incapable of providing grounds for moral or political judgment much less comprehensive programs for social reform. Defenders argue that their aim is both more limited and more modest, namely, to work on the limits of what it is possible to think or to say and thereby to contribute to the emergence of new norms, which may also become bases for judgment. To those who argue that the task of problematizing existing ways of thinking or challenging existing norms is ultimately of limited importance, postmodernists reply that not to do so is to limit the possibilities

for thinking and acting differently. For this reason, they argue, the ethos or *Kunstwollen* of postmodernism should be seen as a necessary element of every genuinely critical approach.

Abstract

This article focuses on the political economy of the reforms undertaken in the contentious climate of fragile democratic transition following the collapse of Soviet-style communism in Central and Eastern Europe (CEE). It first surveys the enormity of the tasks facing the reformers and the historical and political domestic context that shaped the initial debates about reform, and, ultimately, forged the reform pathways. The article then turns to the strong external pressures influencing economic reform, most significantly to those of the European Union. Collectively, these external pressures facilitated structural changes that resulted in highly liberalized and globally integrated CEE economies.

Introduction

After the fall of Soviet-style communism in Central and Eastern Europe (CEE), the countries in the region faced the daunting challenge of rejoining the West. This article focuses on economic reform, which was subject to contentious political debates in the young, and often fragile, democracies. Although local political contexts shaped the initial reform pathways in CEE, these trajectories soon became subject to strong external pressures emanating from international financial institutions, world markets, and most importantly, the European Union (EU). The resulting structural changes turned these economies into some of the most liberalized and globally integrated economies in the world.

Economic Reform Agenda

As the communist system collapsed, countries in the region faced the unprecedented challenge of moving from centrally planned to market economies. Within a very short time span these countries both sought and were expected to reestablish market institutions and rejoin the global capitalist economic order. With the EU at their doorstep, the overarching goal of the 'return to Europe' quickly became the battle cry of reformers from the former Soviet satellite states. It was a goal to which even the less ardent supporters of reform paid lip service. As will become apparent, the task of economic (re)integration was complicated by the type of development these countries had undergone under the communist rule, as well as by the complex institutional evolution that had taken place in the West.

Although the reform priorities, sequencing, and design differed depending on the political context of the country at hand, the list of tasks facing reformers was commonly agreed upon (Mitra and Selowsky: p. 14). First came the need to liberalize prices and trade in order to improve allocative efficiency and create a competitive market environment. Preexisting inflationary pressures, as well as the aftermath of rapid liberalization created the need for anti-inflationary measures that would stabilize the macroeconomy (Roland, 2000: p. 11; Mitra and Selowsky, 2002: p. 14). These included restrictive monetary policy (high interest rates) and balanced budgets. The latter was especially problematic given the legacy of the 'soft budget constraint' (Kornai, 1980). Rather than forcing the enterprises to adjust their production practices, inefficient enterprises that habitually operated in the red were being bailed out by the responsible ministry. Eliminating or severely curbing subsidies and other forms of assistance to both enterprises and banks proved to be an extremely demanding task politically.

A related task was creating an environment conducive to the development of the private sector. This entailed the overwhelming challenge of privatizing existing state-owned enterprises (SOEs), especially the large ones, as well as the encouragement of the entry of domestic entrepreneurs into the market. Another (still ongoing) reform, that went hand-in-hand with privatization but proved to be extremely difficult, was providing an institutional structure conducive to good corporate governance and enterprise restructuring. This, in turn, called for a series of legal and judicial reforms. Yet another set of reforms that were critical to the development of the private sector pertained to banking and to the creation of securities markets, and nonbank, financial institutions. The reform to-do list also included the reform of the tax system and restructuring of public expenditures, as well as the institutional reform of the public sector more generally (Mitra and Selowsky, 2002: p. 14; European Bank for Reconstruction and Development, various years).

Communist Legacies and Challenges to Economic Reform

These daunting reforms were complicated by the type of development transition economies had undergone during the communist system. All of the countries discussed here had large industrial sectors, ranging from 30% GDP in Hungary to 59% in Bulgaria and Czechoslovakia (European Bank for Reconstruction and Development, 1999). More problematic than the sheer extent of these economies' reliance on industrial production was the type of industrial production in which they were engaged. The effort to build a communist economy entailed a massive modernization project where heavy industry, rather than industries producing consumer goods, played the primary role. Because success was measured by

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10126-6

output, and the enterprises did not have a hard bottom line, industries such as steel, heavy machinery, armaments, and chemicals suffered from overcapacity and inefficiency in the context of a market economy. The case in point was Czechoslovakia, where the communist authorities sought to close the developmental gap between the Czech lands (Bohemia and Moravia) – the most industrially developed in CEE – on the one hand, and the largely agricultural Slovakia, on the other. They succeeded, but industrial development took, in part, the form of armaments factories that serviced the needs of the Warsaw Pact. The end of the Cold War rendered these obsolete and greatly complicated the reform process in Slovakia (Wolchik, 1994: p. 64). The monoindustrial towns throughout the post-communist region, where the entire local economy revolved around a single giant enterprise faced particular economic and social challenges.

Despite their shared legacy of central planning, membership in the barter-based, Soviet-sponsored Council for Mutual Economic Assistance, and political dependence on the Soviet Union, the former communist countries did not all begin the reform process from the same starting point. Even though they shared the same basic challenges, their exact nature and severity varied by country. These differences were rooted in the historically contingent nature of communist rule in each country. There are nuanced typologies of communist regimes in CEE that take into consideration the relationship between the communist authorities and society (see Kitschelt et al., 1999). For the sake of simplicity, however, communist regimes can be broadly divided into more 'liberal' and 'orthodox' in their approach to political and economic developments.

The more liberal regimes, most notably Poland and Hungary, allowed for greater personal freedoms than their more orthodox counterparts, and they also engaged in forms of economic liberalization. Both countries allowed private enterprise to exist. Private sector's share in GDP equaled 30% in Poland and 25% in Hungary in 1990 (European Bank for Reconstruction and Development, 1999: pp. 228, 252). The relatively large private sector in Poland resulted from aborted efforts at collectivizing agriculture, which then remained largely in the hands of individual farmers. It also stemmed from limited forms of small private businesses. Hungary's private sector reflected the Hungarian regime's tolerance of the so-called second economy, or parallel markets, where individuals, often using machinery leased from state enterprises, would produce consumer goods undersupplied by the state (Stokes, 1993: p. 81).

Both countries' relative openness to the West also had its price as it led to accumulation of large amounts of foreign debt in the 1970s. The abundance of petrodollars and ease of credit created incentives to engage in a Western loan-financed, large-scale industrial investment project extravaganza. The projects had disappointing results, and the countries were left with the bill. By contrast, Czechoslovakia had very little foreign debt, as did East Germany, which nonetheless benefited from significant (unofficial) West German subsidies. Bulgarian foreign debt only ballooned in the late 1980s while Romania paid off the entirety of its foreign debt as part of its leader's brutal campaign for total independence from the West (Stokes, 1993: p. 143).

The communist-era economic reform efforts in both Poland and Hungary led to partial liberalization prior to system change, but these measures created the need and opportunity for further reform. Partial price liberalization fueled inflationary pressures. So did the self-management of enterprises where the managers faced worker pressures for increased wages. The same was the case in Yugoslavia, which was not a Soviet satellite state and followed its own version of socialist self-management. Interestingly, similar problems also surfaced in the aftermath of Gorbachev's *perestroika* reforms in the Soviet Union, which preceded its breakup.

If the more 'liberal' communist states had already been exposed to some of the elements of rudimentary market principles, they were also westward-oriented in terms of seeking assistance with further reforms. The case in point was the joining of the International Monetary Fund and the World Bank by Hungary in 1982 and by Poland in 1986, and the allowing of the creation of joint ventures with foreign capital. The pinnacle of westward orientation was a move that dramatically flew in the face of communist ideology: the decision of the Hungarian Socialist Workers' Party to attempt to sell more than 50 SOEs to foreign owners in January 1989 (Stark and Bruszt, 1998: p. 54).

Neoliberals and Their Critics

The West indeed took an active interest in the Soviet satellite states as communism collapsed, especially in those in which it had a financial stake, such as Poland and Hungary. Western advisers, most prominently Jeffrey Sachs, flocked to the region and supported the local reformers in their efforts. Although the totality of the reform agenda, outlined above, may not have been controversial, the priorities, sequencing, and the means through which the reforms were to be undertaken differed substantially among countries. They also generated significant debate. The reform choices were closely rooted in the domestic political conditions, as will be outlined in broad brushstrokes below. First, however, we turn to the biggest controversy that plagued practitioners and academics alike during the first decade of transition: the neoliberal approach to reform. Broadly speaking, two camps emerged: neoliberal proponents of the 'Washington Consensus' and their critics.

The neoliberal camp, which dominated the transition process and consisted of both foreign advisors as well as domestic reformers, advocated the primacy of the policy trio of the Washington Consensus: liberalization, stabilization, and privatization. The key was to get the price signals right by eliminating distortions, which called for a quick and comprehensive 'shock therapy' package consisting of liberalizing and anti-inflationary measures. Privatization was to accompany the shock therapy package as quickly as possible because it was seen as a tool to "create market structures to encourage private businesses" (Åslund, 2007: p. 146).

Rapid reforms were considered advantageous for several reasons. First, they would take advantage of the unique 'window of opportunity' offered by the short-lived popular enthusiasm for reform (Balcerowicz, 1995). Given that under shock therapy the material situation of the population deteriorates quickly before it improves, the reformers saw the need to carry out painful reforms before the losers of the reform process had the time to organize to reverse them (Przeworski, 1991).

Rapid reforms would offer two additional benefits that were especially salient in the case of privatization: they would make the reforms irreversible, and they would create a constituency of winners who would support the continuation of the reform efforts.

The dominant neoliberal paradigm was criticized on several counts. First, proponents of gradual reforms argued that these would result in less social dislocation as the poststabilization recession would not be as deep (Przeworski, 1991). Second, institutional economists, sociologists, and political scientists argued that the neoliberals presented a much oversimplified vision of market economy. The frequently cited quote by Jeffrey Sachs that "[m]arkets spring up as soon as central planning bureaucrats vacate the field" (1994: p. xiii) became symbolic of the neoliberals' catchy but simplistic invisible hand approach that ignored the centrality of institutions in market exchange. Some of the fiercest critics even leveled the charge of 'market Bolshevism' as they lambasted the neoliberals for assuming that they could simply use shock therapy to 'install' institutions while ignoring the specificity of local conditions and preexisting institutions (Stiglitz, 1999; Murrell, 1992). Rather, they argued that institutions take time to evolve and are socially embedded. Hence, they were skeptical that any reform blueprint could simply be imposed on what was the supposedly blank slate of transitioning countries. Rather, as a prominent sociologist put it, capitalism was being built not on but *with* the ruins of socialism (Stark, 1992). The local political and social conditions, and the institutions left over from the previous system would determine both which reforms would be adopted and how they would be implemented.

Economic Reform Pathways

Although the neoliberal blueprint became the dominant reform paradigm in policy circles, the extent and the mode of its implementation were rooted in the domestic political conditions. Space considerations preclude an in-depth discussion of individual countries, but the broad brushstroke presentation of reform pathways illustrates the diversity in the paths chosen. Poland, facing significant macroeconomic imbalance, became the path-breaker with its bold 1990 shock therapy recipe, named the Balcerowicz Plan after Poland's finance minister. Due to internal political disagreements over the choice of privatization method for large SOEs, the so-called 'large privatization' was left until later, much to the disappointment of the international financial institutions, and proceeded in a gradual fashion. At the same time, research has shown that, faced with hard budget constraints, SOEs adjusted much better to market conditions than expected (Pinto et al., 1993).

A year later, Czechoslovakia followed with its own shock therapy plan, accompanied by an innovative voucher privatization scheme aimed largely at small and medium enterprises, with sales of only minority stakes in large enterprises. By contrast, Hungary chose the gradualist path, but the rising macroeconomic instability eventually called for a shock therapy package, the so-called Bokros Package (also named after Hungary's finance minister), which was implemented in 1995. The Hungarians were also unique for their initial ability to attract relatively high levels of foreign capital as part of their privatization efforts.

The East German pathway was different altogether as East Germany became absorbed by the much bigger West German economy in the aftermath of the German reunification in 1990 and could take advantage of both West German market and state institutions, as well as of their significant transfer payments. These were very much in order as the East German economy collapsed in the aftermath of a currency union between East and West Germany, which although quite advantageous for the East Germans, had the side effect of making East German industry uncompetitive virtually overnight (Stokes, 1993: p. 185). The reforms in Romania and Bulgaria, on the other hand, proceeded in fits and starts. In both cases, initial stabilization and privatization efforts were significantly compromised by the heavy presence of the communist-era managerial interests that still had the ear – and the purse – of government officials (Ganev, 2007; Gallagher, 2005; Roland, 2000).

Privatization as an Example of Economic Reform Challenges

The preceding account illustrated the diversity of the extent and timing of both macroeconomic stabilization policies and privatization. The privatization experience offers insight into the unique challenges of reforming a postcommunist economy, but also into the importance of regulatory institutions. The challenges of privatization were well summed up by a quip Janusz Lewandowski, the Polish Minister of Privatization, made in 1990: "[p]rivatization is when someone who doesn't know who the real owner is and doesn't know what it's really worth sells something to someone who doesn't have any money" (Stokes, 1993: p. 196). Therein lay the two key problems encountered by reformers. First, given the legacy of central planning, it was difficult to appraise the assets that were being offered for sale prior to privatization. Second, buyers were not easy to come by.

Foreign investors had the money and the know-how to turn SOEs into profitable businesses, but they were initially wary of entering these markets for several reasons. First, they faced uncertainty about the unprecedented reform process, and their unease was not allayed by the limited domestic support for sales of the 'family jewels' to foreigners in the region. Second, foreign investors feared investing in enterprises with excess production capacity, obsolete equipment, overstaffed workforce, and assets completely unrelated to production in their care (company housing units, medical clinics, kindergartens, recreational facilities, etc.). In other words, they needed some form of preprivatization restructuring by state authorities before committing to some of the bigger enterprises. State-led restructuring, and reform (as opposed to excising) of state institutions more generally, were certainly not at the top of the initial reform agenda (King and Sznajder, 2006).

Domestically, individuals with significant financial assets were largely communist party cadres, especially in Poland and Hungary. There, the communist-era liberalization efforts led to significant business opportunities for well-connected, entrepreneurial, communist party members and state security apparatus officials. As a result, many reformers and the population at large, were skeptical of capital sales to individuals. In an

effort to popularize privatization, but also to resolve the problem of equity – after all, state property belonged to everyone under the communist regime and therefore, everyone should now benefit – voucher privatization became a solution to the privatization issue touted by the neoliberal reformers. There were several schemes in CEE. Unlike the Russian one where the workers and managers obtained free shares in their own enterprises, in the Czech (and initially Slovak) variant, all citizens were eligible for buying voucher booklets which they could then use in order to bid on enterprises they preferred. In the Polish case, the eventual, relatively small-scale voucher program provided for citizen stakes only in the holding companies that managed shares of the enterprises they were assigned.

Voucher privatization meant that even though the state would have to forego income from the sale of these enterprises, state assets would get into the hands of private owners, who would, in theory, do a better job of restructuring them than the state could. According to the Czech design, by having to bid on enterprises they were interested in, voucher holders would become personally invested in the success of the reform process while receiving a crash course in market economics. The expected fragmented ownership structure was seen as a temporary phenomenon that would get consolidated over time. The voucher experiment, however, had disappointing results, though its proponents steadfastly defend its achievements. The fiasco of the Russian program of distributing the vouchers to enterprise insiders is well known. However, even the touted Czech program, very skillfully marketed at home and abroad by the Czech Prime Minister Václav Klaus, was gravely plagued by inadequacies of corporate governance. In the Czech case, investment companies that sprung up overnight, bought up vouchers and through cross-ownership of banks and enterprises siphoned off, or 'tunneled out' assets. This, in turn, contributed to the Czech banking crisis of 1997 (Orenstein, 2001).

Voucher privatization remains controversial. Its detractors argue that it led to massive asset stripping and theft. Even in its mildest incarnation in Poland, where the abuses were curtailed by better regulation, the resulting holding companies did not engage in much, if any, investment and had a very passive ownership role (King and Sznajder, 2006). Supporters of voucher privatization, however, insist that poor corporate governance notwithstanding, its results were better than the alternatives (Åslund, 2007: p. 180).

Illustrating the highly political nature of privatization, each CEE state followed its own path to private ownership. While the Czech Republic raced ahead with voucher privatization and also with direct sales to domestic owners, the Hungarian government mostly relied on direct sales and investment tenders, often to foreign investors who felt secure about the stability of the reforms in the country. In Poland, political disagreements over privatization methods led to reliance on bottom-up privatization which consisted of employee and management buyouts, in addition to the eventual combination of limited voucher privatization and direct sales. In Slovakia and Romania, management and employee buyouts also constituted the primary form of privatization while in Bulgaria, privatization took the form of sales (often corrupt) to outside owners. Both in Slovakia and Bulgaria, voucher privatization represented secondary forms of privatization (Åslund, 2007: p. 156).

While the initial round of economic reforms focused on macroeconomic stabilization and privatization, state and regulatory institutions were not on the forefront of the reform agenda. Yet, the importance of state capacity for economic reform, including privatization, became increasingly recognized throughout the reform process (Åslund, 2007: p. 179). Profound transformation of state institutions, including those responsible for regulation, became part and parcel of the EU accession effort, which took off in 1998 following the opening of EU membership negotiations with Hungary, Poland, the Czech Republic, Estonia, and Slovenia. In 2000, these negotiations were extended to Romania, Bulgaria, Slovak Republic, Latvia, and Lithuania.

The Challenge of EU Accession

As stated at the outset of this piece, the idea of the 'return to Europe' was the guiding principle of political and economic reform in CEE. However, EU membership was not immediately on the agenda as EU countries opted for association agreements, also known as Europe Agreements, which established far-reaching trade liberalization with the CEE countries. These were signed between 1991 and 1993. It soon became apparent that these were not enough in the face of clear desire of CEE states for EU membership. Post-Cold War moral imperative on the part of Western European states notwithstanding, the EU realized that eastern enlargement would solidify reforms and therefore enhance the stability of the entire continent. It would also offer new economic opportunities for Western European players on emerging markets to their east.

The institutional gulf dividing the EU from the reforming countries made it apparent that any accession process would be long and arduous. After all, European integration had been ongoing since the 1950s and the postcommunist countries were facing a continually transforming moving target, which was already bound by the body of the so-called *acquis communautaire*. The latter represented a nearly 50-year worth of directives, regulations, and court decisions that were binding on all EU member states (Cameron, 2003). When the EU made the decision to open up membership to CEE states at the 1993 European Council meeting in Copenhagen, it produced the so-called 'Copenhagen criteria,' according to which the new states had to meet three conditions in order to become EU members. The first objective was the stability of institutions guaranteeing democracy, the rule of law, human rights, and respect for and protection of minorities. The second objective was economic and pertained to the existence of a functioning market economy that had the capacity to cope with competitive pressure and market forces within the Union. Third, the new members would have to accept the Community *acquis* and have the ability to take on the obligations of membership, including commitment to adopting the euro as their currency (European Commission, 'Conditions for membership,' http://ec.europa.eu/enlargement/policy/conditions-membership/index_en.htm).

To emphasize the scope of this challenge, the countries that 5 years earlier were still guided by the central planners and

(most of which) had virtually no private property of note, were told that in order to join the EU, they would have to operate on the same market and according to the same rules as the seasoned players coming from such industrial and economic powerhouses as Germany. More details of what it meant to be a functioning market economy and be able to operate on the EU market were spelled out in a 1995 White Paper produced by the European Commission (the equivalent of the executive branch in the EU) that divided the body of EU legislation into subject-related chapters. When the accession negotiations opened with the first tier of reformers in 1998 and with the second one in 2000, these 31 chapters became the basis for negotiations with the Commission.

At the core of EU membership negotiations was the so-called harmonization of national laws with EU law. For each of the thousands of measures comprising the *acquis communautaire*, accession states had to present evidence of how the EU rules would be implemented into their own law at the time of accession. The European Commission monitored the process and evaluated progress made in its annual 'report cards' called the regular reports. Thus, under the Commission's watchful eye, the accession countries were being re-created as states (Cameron, 2003: p. 25). At the same time, although many portray the Commission as imposing its rules on the new member states, some scholars argue that the Commission actually mobilized private and public actors and constructed a nonhierarchical mode of governing (Bruszt and Langbein, 2014). Thus, the new EU institutional requirements became embedded in the national and local conditions.

The Effects of EU Accession and Implications for Capitalism in Europe

Overall, the EU accession process had several profound effects on accession states' economic reform trajectory. On the one hand, among the leading reformers, it strengthened the domestic proreform coalitions but also pushed for reform in areas that were politically difficult (Drahokoupil, 2009; Sznajder, Lee forthcoming). At the same time, among transition laggards, such as Romania and Bulgaria, it tipped the political scale in favor of reformers (Vachudova, 2005; Bohle and Greskovits, 2012).

EU membership thus had a profound effect on the trajectory of market reforms, and it served as a powerful signaling device for foreign investors. After 1994, the initial Hungarian advantage in attracting foreign capital diminished, as the other transition leaders, such as Poland and the Czech Republic, demonstrated their commitment to reform. Moreover, they actively attempted to attract more foreign investment. In fact, the EU effect was so strong that economic studies "underestimated the volume of FDI inflows as the volume of foreign capital stock more than tripled between 1998 and 2004" (Medve-Bálint, 2014: p. 38).

The EU accession process, moreover, also strengthened domestic coalitions that sought to use 'second stage reforms' such as pension privatization, introduction of flat taxes, and cutting of corporate tax rates as a positive signal to attract foreign investors. It should be stressed that with the exception of pension privatization, these reforms went above and beyond what the EU, or even the international financial institutions, such as the International Monetary Fund, advocated (Appel and Orenstein, 2014). Thus, the neoliberal reform trajectory continued beyond EU accession.

The large quantities of foreign investment had profound developmental implications for these countries. They yielded economies that were more transnational than those of the original EU member states, and in which the 'old' EU member states dominate by controlling about two-thirds of the foreign-controlled production (Medve-Bálint, 2014: p. 36).

The banking sector is an extreme, though telling example of the extent of foreign capital in the region. The asset share of foreign-owned banks in national banking systems equals or exceeds 80% in (in rising order): Bulgaria, Romania, Czech Republic, Slovakia, Croatia, Lithuania, Bosnia and Herzegovina, Albania, and Estonia (in the latter, it approaches 100%). In Poland and Hungary, the shares hover about 70 and 65%, respectively. This is in stark contrast to the Western European EU member states. For example, in Spain, Netherlands, France, and Italy the same share comes out to less than 10% (European Bank for Reconstruction and Development, 2012: p. 48). In fact, the heavy overall presence of foreign capital in CEE even led to the economic system in the region being labeled as 'dependent market economies,' where foreign capital and its imported institutions represent the principal coordinating mechanism in the economy (Nölke and Vliegenthart, 2009).

Even though these countries' economies are transnational, some scholars highlight existing differences in their socioeconomic attributes. Dorothee Bohle and Béla Greskovits, for example, argue that putting the label of "dependent market economies" does not reflect the salience of diverse kinds of foreign investment, whether financial capital or investment in the country's industrial production base (Bohle and Greskovits, 2012). Second, various countries struck different types of balance between following the precepts of neoliberalism and attempting to preserve social cohesion and political legitimacy. As a result, countries can be divided into the neoliberal type in the Baltic states and – belatedly – Bulgaria and Romania, the embedded neoliberal type among the so-called Visegrád countries composed of the Czech Republic, Hungary, Poland, and Slovakia, and the neocorporatist type in Slovenia.

Thus, whereas the Baltic states combined radical market reforms with very limited compensation for the heavy social costs of transformation, the Visegrád states searched for social cohesion in the face of neoliberal reforms. Moreover, the former largely shut out organized social groups from democratic decision-making, but the latter were more inclusive – if less efficient – in their reform efforts. Finally, Slovenia stands apart as its marketization strategy was the least radical, most compensatory, and least exclusive, as it followed the principles of democratic corporatism that brought state, business, and labor together in search of compromise solutions (Bohle and Greskovits, 2012).

The Impact of the Financial Crisis and Future Challenges

The new, transnational capitalism established in CEE faced its biggest challenge yet during the onset of the global financial crisis. It hit the region early, prior to the emergence of Greece's financial troubles, and dealt a harsh blow to CEE economies.

However, the effect of the crisis was not uniform, and it was very much tied to the type of foreign investment – whether through the financial sector or through manufacturing and exports – that dominated in the countries at hand (Bohle and Greskovits, 2012; Myant and Drahokoupil, 2012). As scholars have shown, countries belonging to the neoliberal type were, among other external imbalances, particularly vulnerable to 'financialization' or the dependence on foreign finance to support bank loans, which left them helpless when foreign capital pulled out. On the other hand, the embedded neoliberal regimes (and, to lesser extent, Slovenia) were less exposed to capital flight, as foreign direct investment was more concentrated in the export-oriented manufacturing sector. These sectors were hit hard when foreign demand fell, but they bounced back rather quickly due, in no small part, to the fairly strong German economic growth in 2010 and 2011 (Bohle and Greskovits, 2012; Myant and Drahokoupil, 2012). Hungary stands out in this regard, as it was very negatively affected by the high share of foreign currency-denominated loans to private households.

The transition economies have weathered the economic and financial crisis quite well in that the economic institutions in place proved resilient in the face of tremendous pressure. At the same time, the crisis had several effects on the region. First, the enthusiasm for neoliberal reforms waned and some of them were reversed. Overall, the level of policy liberalization fell, compared to the one from before the crisis (Jacoby, 2014: p. 68). The extreme case is that of Hungary, where the populist government of Viktor Orbán's FIDESZ party has thrived on antiforeign capital rhetoric and took punitive actions. These included forcing foreign banks to covert foreign currency-denominated mortgage loans to forints at a disadvantageous fixed rate. Second, some neoliberal policy reversals took place, mainly in the area of pension privatization. In Hungary, pension privatization was reversed, while the Polish government markedly reduced the amount of money allocated to the private pension accounts, thereby increasing the share of state-held assets (Appel and Orenstein, 2014: p. 26).

Third, the crisis also led to questioning of the desirability of membership in the Eurozone, which was one of the commitments made during EU accession, albeit this response was not uniform. The small Baltic states that were particularly vulnerable to boom and bust cycles sought quick membership in the Eurozone, with Estonia joining in 2011 and Latvia in 2014. Lithuania is set to join in 2015. However, in Hungary, joining the Eurozone was placed on hold indefinitely, only in part because the government is not close to meeting the strict membership criteria. At the same time, the Czech Republic has encountered domestic skepticism of membership, as did Poland. In Poland, the initial postcrisis skepticism has most recently been replaced by clear signals from the current government, the President, and the head of the Polish National Bank that Eurozone membership would further embed Poland in the Western institutional framework. This is seen as an additional security measure in the face of Russia's increasingly hostile stance vis-à-vis the EU.

Reflecting on the progress made over the past quarter century, the countries in CEE have made incredible strides in terms of integrating with the Western economic and political order. The reforms have certainly been stimulated along the way by the process of European integration. Yet, although the economic divide between the 'West' and 'East' has narrowed, the gap resulting from the historical underdevelopment of the region has not yet been bridged. Further progress will require overcoming deeply ingrained obstacles such as corruption but also attracting investment that will spur innovation (Epstein, 2014: p. 31).

Postsocialist Societies

Maya Grekova, Sofia University 'St. Kliment Ohridski', Sofia, Bulgaria

Abstract

The term 'postsocialist societies' is applied to societies that were formerly identified as socialist and that have since renounced the socialist course of development since the 1989–90 changes in government. This classification is practically void of meaning as it defines these societies vis-à-vis their past – as societies in transition, which regard themselves, and are regarded, as being in a process of democratization and marketization, and building a civil society. Differences rooted in the history of the transformation of the respective societies into socialism, as well as in their history as socialist societies, have appeared in the course of this transition. Notwithstanding all differences in the pace of transition and in the current or future hardships of postsocialist societies, several common problems attract the researcher's attention.

Definition

The term 'postsocialist societies' itself raises a serious problem: Its use implies that societies that were considered (called themselves or identified as) socialist, and that have renounced the 'socialist course of development' since the 1989–90 changes in government, have no distinctiveness of their own but still are defined by their past. These societies are classified in one and the same group, defined in one and the same way from the perspective of their past – their existence as 'socialist societies' – which they have renounced. On the other hand, this definition from the perspective of their past suggests that they are presumed to be societies in the course of self-identification – seen as being in transition from totalitarianism to democracy, from centrally planned to market economy – which have embarked on the arduous course toward building civil society.

This raises a serious question of the possible criteria by which a concrete national society would shed its 'postsocialist' label; that is, ultimately would have defined itself and be defined from the perspective of the present rather than of the past. At what stage does the present existence of the respective society provide sufficient grounds for regarding it as a society with sustained development based on values asserted in it (and shared by) its citizens?

Changes in the form of government are a necessary but not a sufficient prerequisite for radical restructuring of social life as well as for significant and sustainable changes in the concepts of the world, human relations, and individual actions. That is precisely why the term used is 'postsocialist societies' rather than 'postsocialist states.' The form of state government may or may not be socialist, whereas the declared renunciation of the 'socialist course of development' in itself does not free a society of the values, ideas, and expectations accumulated over the years, nor of the established relations and groups, and the very attitudes to and mechanisms of their establishment. At the same time, the course of self-identification of the 'postsocialist societies' is indefinite – their point of departure is known, but one cannot know for sure what they ultimately will become.

This is a generalization only, because the majority of 'postsocialist societies' (those in Europe) are expected to embrace precisely democratic values, a market economy, and civil society as the pillars of self-identification. Most of these societies have not merely declared this but are making real progress in this respect. They apparently are aware that they will no longer be labeled as 'postsocialist societies' once they complete the process of accession to the European Union (EU). In other words, for those national societies, the criteria of recognition of a completed process of self-identification are the same as the criteria of fully fledged EU membership, which means that they already have chosen a course of development and that their development is predetermined – all they have to do is attain the ultimate objective. Postsocialist societies outside the purview of the EU, of course, face different problems.

Differences Stemming from the Past

The term 'postsocialist' creates a false impression of uniformity of the societies in question (even though this definition is indefinite itself) and, respectively, of uniformity in the process of departure from their previous development as socialist. This idea is based largely on the previous term 'socialist societies' that has the ideological function of hiding or belittling the internal distinctions of the respective 'socialist societies,' as well as of rendering as entirely insignificant, from the perspective of their existence as 'socialist,' the differences in their previous development and the concrete process of their 'transformation' to socialism. They are 'socialist societies,' and all details of the history of their transformation to socialism and of the national specificity of their existence thus are deemed insignificant. Yet it is precisely those formerly 'insignificant' differences (declared and considered insignificant, but to a large extent also virtually insignificant from the perspective of 'the general line' of development, of the rallying of the respective societies into the 'socialist camp') that largely determine the form of renunciation of the 'socialist course of development' constituting significant accelerators or impediments (Fowkes, 1999; Nagle and Mahr, 1999; Offe, 1996; Rose et al., 1998). Generally speaking, these national variations of the road to state socialism are significant determinants of the national specificity of the existence of the concrete societies as 'postsocialist,' as well as of the pace and consistency of the transition period, of the ways of reaching national consensus on the parameters of the change, and of the actual concept

and definition of 'national consensus' (for a consistent pursuit of such an understanding, see Brown, 2009; Burawoy and Verdery, 1999; Priestland, 2009).

Forgetting the history of the formation of a particular nation-state and the way in which it 'embarked on the road to socialist development' – or failing to take into consideration the influence of national specificity on the existence of the respective society as socialist – usually results in overemphasizing the impact of international institutions (economic and financial, as well as political) whose actions are guided by economic and geopolitical interests, as well as of the role of the personality of the respective political leaders (in the concrete 'postsocialist society'). Thus, the changes and their pace in 'postsocialist societies' (especially in Europe) prove directly and crucially dependent on foreign interests or the individual abilities of politicians. Consequently, individual and group responsible action proves impossible or, rather, pointless. Even if it were possible, its ineffectiveness is justified readily by counteracting external forces or inactive internal factors.

Social scientists, among others, are accountable for the formation of explanatory models centered on these two variables. To explain the transition period and its problems, they deviate from their scientific position under pressure from their partisan allegiance; concentrate on the present, forgetting history; resort to biased selection of historical facts to legitimate their interpretation of events; build a macroexplanatory model of transition in general, ignoring national differences; or cite separate facts or data from opinion polls without the historical-theoretical framework requisite for their interpretation.

The production and public presence of such 'explanatory models' of the problems of the transition period generate further tensions in the postsocialist society. First, they are explanatory and deliberately created for the purpose of introducing ultimate clarity among ordinary citizens about current developments. Second, they are even more convincing on the strength of their authors' scientific prestige. Third, they are qualitatively heterogeneous – rather than just different – interpretations, and at the same time each one of them claims to be the only truthful interpretation. This lopsided way of 'understanding' developments, history, and the origin of problems in social life, as well as events and political actions, proves to be yet another factor (along with political allegiance and social position) that antagonizes individuals and groups.

Present Similarities or Key Problems of Transition

Two ranges of problems may be identified: Problems associated with identity and problems associated with social interaction. Although they are not confined to postsocialist societies only, here these problems have acquired special significance and a specific form. They may also be generalized as 'political,' 'economic,' or 'social' from a macrosociological perspective on social reality, on the processes occurring within the latter, and on their specific intertwining. The microsociological perspective proposed is based on the understanding that the restructuring of a society that has renounced socialist principles and norms (or, generally speaking, any society in the course of self-identification as something that is qualitatively different) proceeds from the presumption of the major significance of the changes in the ways of thinking and action and is impeded seriously by the continuing effect of previous models of thinking of the world and the others, patterns of behavior, and mutual relations of individuals and groups.

Problems of Identity

These problems concern apparently quite heterogeneous phenomena that, however, are experienced by the individual or group in a similar way as problems of self-identification: from 'nationalism,' which has become indicative of postsocialist societies, to 'unemployment' and 'poverty,' which rarely are treated as problems of identity (defined foremost as social and economic problems).

The preoccupation with national and ethnic identity, which apparently has divided (albeit in quite different ways) the postsocialist societies, stems from two specific features of the ideology upheld in socialist society: National and ethnic specificities within the boundaries of a separate state and between the states from the 'socialist camp' are insignificant – the significant self-identification is 'socialist citizens' (which does not mean that ethnocultural differences have been forgotten within the separate states or that they never were an undisclosed reason for actual social inequality). Accordingly, the significant difference is associated directly with significant self-identification – the localization of everything 'strange' there, that is, beyond the 'iron curtain.'

The disintegration of 'the camp' and the fall of 'the wall' dividing the two worlds, inevitably rejecting the validity of significant self-identification and difference, generated the need for 'national' self-identification. Whereas the question 'Who are we?' focuses the attention inward on the 'national community' and back in history, on the national community's existence and formation before its 'depersonalization,' the attempt at defining 'us' (who are united within a state) has exposed differences and has led to intolerance and discrimination against different ethnic and religious minorities (Opalski, 1998; Rupesinghe et al., 1992; Tismaneanu, 1998). This process, common to all postsocialist societies, has acquired qualitative specificity (largely determined according to the constitution of the respective 'socialist societies'): from violent disintegration of multinational states (the Soviet Union and Yugoslavia), to the peaceful division of Czechoslovakia, to the more or less conflict-ridden confrontations between 'national majority' and 'ethnic–national minorities' in Bulgaria, Romania, Hungary, and elsewhere. Yet the problem of emphasizing internal differences (by origin, language, religion) has remained common despite their qualitative specificity: Internal differences that are thought to be significantly distinctive of people to the point of their existence within more or less closed groups, and perception of respective individuals as significantly predetermined by their 'belonging' to those groups. Regardless of the self-perception of the respective individuals, 'the others' ascribe identity to them and treat them (engage in or avoid relations with them) from the perspective of this identity.

The problematic process of identification with European (Western) values unfolds against the background of these 'internal' problems of self-identification and ascription of identity. This process is problematic mainly because of the

complex and contradictory combinations of three commonplace ideas: 'We are European,' 'We have had a tragic destiny (not without the involvement of the West), now the West should help us become like them,' and 'Once we are admitted to the EU, we shall become Europeans.' Although the images and expectations underlying the apparently unambiguous images of Europe and the West and the notions that 'we are European' and 'we shall become Europeans' are quite different, their focus is arguably on 'becoming like them.' Conversely, the principal dimension of the process of 'becoming' is the expected well-being.

This is not accidental. And it is directly associated with another aspect of the identity crisis in postsocialist society – unemployment and poverty (Kornai, 1995, 1997; Michta and Prizel, 1992). These two related but different problems are no doubt indicative of the scope of the economic crisis, but their personal aspect concerns the deepest layers of individual identity, largely because the status of being unemployed is unfamiliar, virtually absent in the experience of the 'socialist individual,' whereas poverty is a process that individuals who have found themselves in a postsocialist society do not associate with democracy and a market economy.

Problems of Social Interaction

The change (or, rather, the orientation toward change) in the principles of organization of social life triggers tensions at all levels of social interaction. At the level of the individual, these tensions take the form of a large-scale crisis in human relations. At the level of institutionalized interactions, they are manifested in 'corruption' of significant proportions.

The 'crisis in human relations' could be reworded, too, as a moral and a political crisis as well as a problem of interethnic relations. For the everyday person, however (insofar as we can talk about an everyday person in a world in which what is taken for granted is always questioned), this problem appears as tensions in relations, as a failure to understand the 'other' (or vice versa), avoidance of certain others, isolation of and from strangers, and so forth. That problem covers the whole range from the closest social environment – family, relatives, friends – to neighbors and colleagues, to functional relationships with anonymous others.

The problem generally defined as a 'crisis in human relations' actually results from the intertwining and superimposing of diverse manifestations and echoes of political, economic, and cultural values and other changes on the macrosocial level. The realized opportunity of being different in our political preferences and allegiance and in our economic status, as well as of choosing between different cultural models and of adhering to different values, inevitably has destroyed established models of family, friendly, neighborly, business, and interethnic relations. Yet new models may appear only as a result of a long and complex process of construction, mutual adjustment, and assertion. They are not something that can be borrowed (imported, grafted) or something that becomes valid simply because it is (or appears to be) better.

Similar to nationalism, corruption has become emblematic of postsocialist societies. And just like nationalism, corruption is not an unfamiliar phenomenon in Western societies. Moreover, corruption is an affliction of democratic society insofar as the latter has sufficiently large opportunities for responsible decision making, instead of the strictly prescribed rules for any action that are typical of any totalitarian society and relieve its members of responsibility. Yet the opportunity for responsible decision making is also an opportunity for irresponsible action. In the postsocialist society, the complex and contradictory intertwining of still-effective old schemes of control and decision making, and the deficiency of new norms (both on the institutional level of laws, regulations, ordinances, and so on and on the level of individual and group consciousness, including role models, values, and notions) turn corruption into an epidemic. The affliction acquires huge proportions due to, inter alia, the internally contradictory perception of corruption: on the one hand, it is seen as an inevitable relation in a situation of transition, of reformulating and reregulating of institutions, social positions, rules, and so forth, which are invisibly present in the social sphere and are manifested in status, security, possessions, and wealth of those who have effected the replacement. On the other hand, corruption is embodied in the bribe-taker, insofar as bribe-takers are those who have rare resources, by rule of power, which many other persons would like to use. The bribe-giver, however, is simply one of many: Bribe-givers do not control the rules of replacement, the way of negotiations, the size of the bribe to the bribe-taker, they simply are the person who has happened to be in this position and, in this sense, anyone may end up in this position. Thus, the bribe-taker is regarded as an irresponsible power-holder and the bribe-giver as anyone of us forced by the circumstances and therefore not responsible for their involvement in relations of corruption.

From Postsocialist Society to EU Membership

The general orientation that all European postsocialist societies indisputably follow is democratization of social life, market economy, freedom of speech and association, multiparty political system, and human and minority rights. This orientation was anticipated to lead the respective states to full membership in the EU, which, once achieved, would secure an end to their postsocialist, transitory, and undetermined state of being. In different years, the European postsocialist states declared their wish to join the EU, engaged in accession negotiations, and acquire the status of candidates for membership. By June 2012, the majority of these countries already had been accepted as full member states of the EU. The foundation for the EU enlargement was laid by the Copenhagen criteria adopted by the EU in 1993, which should be met by the candidate countries to make them eligible for full membership in the EU (see Copenhagen criteria, at http://www.europarl.europa.eu/enlargement/ec/pdf/cop_en.pdf).

Former Postsocialist Societies – New Members of the EU

On 1 May 2004, the Czech Republic, Slovakia, Poland, Hungary, Estonia, Latvia, Lithuania, and Slovenia (together with Malta and Cyprus) joined the EU. It was assessed that they had implemented the Copenhagen criteria. Separated from this group were Bulgaria and Romania, which were evaluated to not

have covered all criteria and, respectively, their accession was postponed and took place on 1 January 2007.

The successful implementation of the criteria for integration in the EU does not mean that the differences among the postsocialist states, as well as between them and the old member states, have been erased. During the socialist regime, the differences among the socialist states were presented as insignificant from the viewpoint of 'building socialism' and 'the bright communist future.' Even in the socialist era, however, there were emblematic differences: The Hungarian revolution of 1956 and the Prague Spring of 1968 were examples of publicly articulated resistance against the communist regime, which were suppressed by the military force of the Warsaw Pact; Romania under Nicolae Ceaușescu (1918–89) refused to join the bloc's military intervention in Czechoslovakia in 1968 but endured his extremely repressive totalitarian dictatorship in the following decades; Hungary, Czechoslovakia, and the German Democratic Republic (GDR) achieved considerable economic development and constituted a 'showcase of socialism'; the Socialist Federal Republic of Yugoslavia dominated by Serbia under the leadership of Josip Broz Tito (1892–1980) maintained a relatively autonomous ideological standing and pursued an economic policy that deviated from the socialist principles; Albania was concealed from and for the world as a stronghold of Enver Hoxha (1908–85). In addition to these differences among the states in the socialist period, other specificities should be taken into account, including specificities that originated in the presocialist times and later were downplayed as insignificant for the socialist development of the respective societies. These specifics include the traditionally strong influence of Catholicism in Poland, the imperial past of Czechoslovakia and Hungary within the Austro-Hungarian Empire, and the legacy of Bulgaria as a former domain of the Ottoman Empire. These differences, among others, exert their impact on the national specificity of the process of 'transition' despite the shared socialist past of the countries, as well as on the processes of overcoming the socialist legacy and joining the EU. Precisely these differences among the European socialist states as well as between the variety of socialisms in European and non-European contexts increasingly attract the research interests of social scholars (Blokker and Dallago, 2009; Boje et al., 2007).

The Difference between Postsocialist and Former Socialist Societies and Countries

The integration of the former socialist states in the EU shifted the emphasis in their self-identification: They already have completed the process of transition and are no longer postsocialist societies but rather are democratic societies that have severed all links to their socialist past. Regardless of the political, economic, and social problems that to a varying degree characterize the contemporary situation of all European democratic societies, the former European socialist states are now part of a united Europe. Differences still exist among them; for example, Bulgaria and Romania are not yet members of the Schengen Area of free movement because they are not in compliance with certain political criteria for joining; Bulgaria, the Czech Republic, Latvia, Lithuania, Hungary, Poland, and Romania are not yet members of the Euro-zone because they not in compliance with certain economic criteria. These are differences, however, that newly accepted EU member states presumably are capable of overcoming.

The term 'postsocialist societies' still is used as the current designation of the societies or states that so far have not been accepted into the EU: Croatia became a member of EU on 1 July 2013; Serbia, Macedonia, and Montenegro are candidates for membership; Albania, Bosnia and Herzegovina, and Kosovo are potential candidates. With the exception of Albania, these are all states that declared their independence and subsequently were recognized by the EU after the military disintegration of the Socialist Federal Republic of Yugoslavia.

The designation 'postsocialist societies' labels an obscure transitory condition. 'Former socialist states,' for its part, designates a state regime that was left behind in history.

Are Non-European (Former) Socialist Countries Postsocialist Societies?

If we apply the previous definition of a postsocialist society, we should assume that China, Vietnam, and Cuba are not postsocialist societies. In their state governance, they continue to maintain the socialist ideology and praxis, whereas the repudiation thereof is a necessary, although insufficient, condition to determine a particular society as 'postsocialist.'

The worldwide changes, in the course of which the former socialist countries in Europe, the countries established after the disintegration of the Union of Soviet Socialist Republics, and Mongolia embarked on a transition toward democratic governance and market economy (by different means and with different pace and success), no doubt have an impact on the countries that adhere to state socialism. Among them, the development of the People's Republic of China is certainly the most interesting case from the viewpoint of the ongoing socioeconomic transformations. This is similar to the development course of the Socialist Republic of Vietnam, which, however, has a much weaker presence on the world economic and political stage. These transformations are induced largely by the existence of private business – albeit under the umbrella of the state authority, the Communist Party – which emerged in the end of the 1980s and by now has absorbed a great part of the productive capabilities of the country and become an important constituent of the global economy (Brown, 2009; Tsai, 2007). What is the appropriate way to define a society, in which socialist rule, capitalist economy, and agriculture based on small family property and traditional–patriarchal values and relations are all in place in a relatively unproblematic coexistence (Brown, 2009; Nee and Opper, 2012; Szelenyi, 1998)? We can conceptualize it as a 'transitional society' inasmuch as it remains unclear in which of the familiar types of society this 'transition' will end and insofar as it might be assumed that the present combination of socialist rule, capitalist economy, and traditional social relations holding together the majority of the population cannot be sustained in time.

The case of Cuba is different. In the Republic of Cuba (the 'Island of Freedom'), a socialist society continues to be

reproduced despite certain changes in the state governance that in no way contest its fundamental socialist principles and values, and a limited 'openness' to the world that tolerates access while resisting outside influence.

Post-Traumatic Stress Disorder

J David Kinzie, Oregon Health and Science University, Portland, OR, USA

This article is a revision of the previous edition article by M. Newman, volume 17, pp. 11881–11885, © 2001, Elsevier Ltd.

Abstract

Since the description of post-traumatic stress disorder (PTSD) in the second edition of Diagnostic and Statistical Manual of Mental Disorders (DSM-II) in 1980, PTSD has become a well-established and well-researched clinical condition. DSM-5 further refined the criteria but it is not consistent with the proposed 11th version of International Classification of Diseases criteria for PTSD. PTSD is fairly common and its prevalence increases with increase in traumatic events and is associated with alcohol abuse, depression, hypertension, and diabetes. The general theory of symptoms of PTSD is that the uncontrollable state of fear persists even after the threat is gone. Recent biological research indicates that biological factors such as genetics increased activity in the amygdale, reduced cortisol, and hyperactivity of adrenergic response occur in chronic PTSD. Psychological treatment has usually been trauma-focused behavioral therapy, but it is not clear if it is necessary to focus specifically on the trauma rather than supportive therapy of current life stressors. Medicine can reduce major symptoms such as nightmares, irritability, sleep disturbances, and needs to be used with psychotherapy. Future research will provide better understanding and treatments of this often chronic disabling disorder.

Introduction

Since ancient times, psychological traumas have been described in various literature. The Sumerians in 2000 BC lamented the destruction of Nippur, leaving the population in total anguish and suffering. There was not a good clinical description of psychological effects of trauma until the railroad spine syndrome, which was described by Erikson in 1887 (Kinzie and Goetz, 1996). The symptoms from railroad train accidents included anxiety, memory and concentration problems, irritability, disturbed sleep, sudden alarmed distressing dreams, and multiple somatic complaints. Similar complaints also include chest pain, rapid pulse, and shortness of breath were noted during the American Civil War. Natural disasters, such as earthquakes and volcano eruptions, resulted in clinical descriptions of acute reactions and even psychosis with clouded consciousness, amnesia, disorientation, fearful affect, hallucinations, and perceptual disturbances.

An increase in post-traumatic symptoms were described during and after World War I under the name 'shell shock,' which later also became known as 'war neurosis.' This was a heterogeneous group of symptoms, which were originally explained by organic brain damage but was later known to have mostly psychological cause. Early theory of post-traumatic stress symptoms were dominated by Freudian psychology, which was a neurosis related to sexual conflict. However, this was not universally accepted because neurosis emphasized intrapsychic processes and downplayed the effects of the trauma itself. World War II saw many severe reactions to war, namely 'war fatigue,' 'war neurosis,' and 'soldier syndrome,' and these had marked similarities to those described previously to traumatic events. Concentration camps of the Holocaust provide further evidence of severe psychological impairment from very traumatic events including mass execution, brutality, starvation, and humiliation. Among the symptoms were restricted mental horizons, indifference, and irritability. The symptoms after the concentration camps were diagnosed as Gross Stress Reaction in the first edition of Diagnostic and Statistical Manual of Mental Disorders (DSM-I) and usually involved a poor prognosis.

No similar reaction diagnosed in DSM-II, but in DSM-III edition printed 1980 after Vietnam War veterans returned there was a description of the major aspects of post-traumatic stress disorder (PTSD) under the category of anxiety disorders. The symptoms had broad categories of reexperiencing avoidance and autonomic arousal. The DSM-IV specified the trauma criteria in which a person experiences, witnesses, or confronted with events involving actual threatening of death or serious injury or the psychological integrity. In conjunction with the event, the person who suffered responses must include intense fear, helplessness, or horror with multiple symptoms of persistent reexperiencing including nightmares, distress, intrusive thoughts, and intense psychological distress when exposed to external cues. Persistent avoidance was another group of symptoms involving numbing of response or avoidance; effort to avoid thoughts and avoid activities reminding one of the traumas they experienced, an inability to recall important aspects of the trauma, decreased interest in participation of significant activities, feeling of detachment, or enstrangement from others. Hyperarousal symptoms involve difficulty falling asleep or staying asleep, difficulty concentration, irritability, hypervigilance, and exaggerated startle response. The duration of these symptoms lasted longer than 1 month and caused significant impairment in social, occupational, or other important aspects of functioning. PTSD was separated from acute stress disorder in which there are dissociative symptoms and the disturbances last for a minimum of 2 days and a maximum of 4 weeks.

DSM-5 of the American Psychiatric Association Diagnostic and Statistical Manual published in 2013 involved major changes in the diagnosis of PTSD. In DSM-5, PTSD was included in new category not under 'anxiety disorders.' It is in a separate chapter called 'Trauma and Stress-Related Disorders.' This chapter specifically is for diagnosis in which a traumatic event resulted in the onset of symptoms. In DSM-5, the removal of the subjective response, which was a fear-based response (fear, helplessness, or horror), because research

indicated that these fear reactions did not happen for many people who subsequently developed PTSD. Summarized here, there must be at least one exposure to an actual or threatened death, serious injury, or sexual violence. Criteria A: presence of at least one intrusive symptom such as recurrent memories of distressing dreams. Criteria B: at least one symptom of persistent avoidance. Criteria C: at least two negative alterations in mood or cognition such as the inability to remember important aspects of the traumatic events or impairment in relationships and is not associated with substance use. Criteria D: hyperarousal symptoms such as irritability hypervigilance with exaggerated startle response. Criteria E: symptoms muse last longer than 1 month and must cause significant impairment in social, occupational, and other important areas of functioning.

DSM-5 notes that cultural factors may influence the expression of symptoms and also resilience. Certain cultures have more exposure to cultural events such as genocide and impact of trauma may influence the entire social–cultural society such as inability to perform funeral rituals or residing in population of unpunished perpetrators.

Early research indicates that the DSM-5 changes probably do not significantly change the prevalent rate of PTSD. A controversial issue was to include a category called Complex PTSD in DSM-5. This would involve events that are severely traumatizing including prolonged torture or in the developmental stages, i.e., severe child abuse. Eventually, it was ruled that there was not enough evidence to support this category despite strong clinical experience that some forms of traumas are so severe that they involve special consideration, treatment, and prognosis (McDonnell et al., 2013).

The WHO international classification of diseases (ICD), eleventh version, has proposed two related diagnosis: PTSD and complex PTSD. PTSD symptoms include core elements reexperiencing of traumatic reminders and excessive hypervigilance or exaggerated startle response. The syndrome has fear at its heart and conceptualizes PTSD as a fear condition.

Complex PTSD has basic PTSD symptoms as well as three domains of self-organization, affective dysregulation, negative self-concepts, and interpersonal problems. A latent profile analysis (Cloitre et al., 2013) confirmed that chronic traumas was more predictive of complex PTSD and that complex PTSD had more impairment than PTSD.

The development of ICD-11 and DSM-5 were to harmonize the two classification symptoms of mental disorder. As shown above, the symptoms are markedly different have the potential to cause confusion to clinicians, patients, and researchers (Bisson, 2013).

Prevalence, Comorbidity, and Prognosis

Although many people (up to 90%) experience a traumatic event in their lifetime, most do not develop PTSD. By the National Comorbidity Survey (Kessler et al., 1995), the lifetime prevalence of PTSD is 7.8%. It is higher among women traumatized by rape and sexual molestation and is also higher among men with combat exposure. A recent study has a lifetime prevalence rate at 10.1% and a 12-month prevalence rate of 3.1% in 2012 (Kessler et al., 2012). Report by the US Military personnel are thought to be 14–15% for lifetime prevalence of PTSD in combat veterans. A study of torture survivors who are applying to the United States as refugees or asylum seekers, the rate of PTSD is 80% by treating clinicians' evaluation.

PTSD is highly comorbid with other disorders. In a national survey (Kessler et al., 1995), about 49% had comorbid major depression. Alcohol abuse or dependence was 52% among men and 28% among women. In clinical interviews, it was found that 63% of Vietnam veterans with PTSD had comorbid major depressive disorder (MDD) as compared to 45% of Afghani/Iraqi veterans (Pukay-Martin et al., 2012). Among torture survivors, the comorbid rate of MDD was 62% (unpublished data, National Consortium of Torture Treatment Programs USA). The latter populations had almost no alcohol abuse or dependence, probably related to the population predominantly Muslim and Buddhist.

For many, the course of PTSD is quite chronic. More than a third of people with index PTSD have failed to recover after many years and it has shown among follow-up studies of patients with PTSD that it has a fluctuating course with remissions and exacerbations under stress (Chopra et al., 2014). Fluctuating course, especially among the elderly, gives an overall lower quality of life. It is now known that veterans of recent wars in Afghani/Iraqi region have a high suicide rate. Studies have shown that veterans with PTSD and major depression have a high suicidal ideations and that depression may be the mediating factor of suicidal behaviors.

There is increasing evidence that chronic PTSD can significantly increase the association with type 2 diabetes (Lukaschek et al., 2013). In addition, there is evidence it may increase the blood pressure and hypertension as a consequence of the arousal symptoms of this disorder (Paulus et al., 2013). Furthermore, evidence has accumulated that childhood and probably adult trauma can increase the risk of cognitive impairment in old age, leaving a higher prevalence of dementia in this group (Burri et al., 2013).

In summary, it appears that PTSD is fairly common in a national sample population. The prevalence of PTSD increases when an increase of traumatic stress happens, such as it would be for combat veterans and particularly torture victims. In national studies, women have more prevalence of PTSD than men, and in both, it is highly comorbid with MDD. In American veterans, PTSD is correlated with alcohol abuse, but not with samples from torture victims. It is now known that suicide is a long-term concern of veterans with PTSD and depression, and now, diabetes, hypertension, and dementia may also be a long-term consequence of PTSD.

Etiology

PTSD is the only major psychiatric disorder for which there is a known cause; that is a traumatic event that is a threat to the personal integrity or life of an individual. There has been a movement to go away from an intrapsychic dynamic of neurotic mechanisms, as was emphasized in earlier psychological literature, to one where there is an emphasis on the real trauma itself. Using a Pavlovian model, it is thought that the response to traumatic events occurs not just at a psychological level, but also at a physiological level due to classical conditioning. PTSD, with its continuation of symptoms, is consistent

with the uncontrollable state of fear. In this model, PTSD represents a failure of extinction. Recent research (Bryant et al., 2013) document that PTSD has a complex and fluctuating course, 44% of these 24 months after the event had PTSD, but did not meet criteria at 3 months. Part of this was explained by the number of stress events experienced between 3 and 24 months. This finding is consistent with a sensitization model, which suggests that an excessive response to a subsequent less-stressful event occurs because neural pathways are sensitized after an initial traumatic event. Sensitization model helps explain delayed onset and reactivation symptoms. (For a review of memory mechanisms involved in PTSD, see Parsons and Ressler, 2013.)

Biological Factors in PTSD

One of the most robust biological findings in PTSD is elevated heart rate during both trauma cue studies and resting states. They support the idea that PTSD is associated with elevated psychophysiology (Pole, 2007). As mentioned before, hypertension is found in many PTSD patients (Paulus et al., 2013). Other biological factors have been intensely studied in PTSD and have been summarized in two expert's reviews (Pitman et al., 2012; Sherin and Nemeroff, 2011).

Genetics

Recent estimates are that more than 30% of the variance associated with PTSD is related to hereditary components. These genetic factors are common to other major illnesses: depression, anxiety, and panic disorder. The genetic influences on PTSD are probably polygenetic and at least 17 gene variances have been associated with PTSD. These have been involved in various central nervous systems. There is a lack of consistency of association of specific genetic variances of PTSD, which may be explained by the modification of the other genes or environmental factors not accounted across studies, for example, extreme traumatic stress. Further genome-wide association studies perhaps offer the best opportunities to identify novel 'true-untrue' variances in PTSD. One current concept from genetic studies is that the effects may not directly be the result from the trauma itself, but may predispose to trauma or symptoms. Predisposition may be involved in personality traits in risky behavior, increased violence, or the expression of symptoms once trauma has been occurred. Genetic factors may interact with environmental factors to cause PTSD. A study found that a stress-related gene (FKPB5) is a polymorphic variant, which interacts with child abuse severity as a predictor of adult PTSD (Binder et al., 2008). There is also evidence that the serotonin transporter gene, which regulates serotonin, and thus emotional response, is involved in a PTSD system. However, there are contradictory results, which specific variants of the serotonin transporter gene are involved in PTSD in moderately but not severely traumatized individuals.

Imaging Studies

In magnetic resonance imaging (MRI) studies of PTSD, the most consistent finding shows lower volume of the hippocampus and a lower volume of the central prefrontal cortex. There is a controversy whether the small hippocampus is a result of traumatic exposure or rather represents a risk factor for PTSD that is of genetic or environmental origin. Interesting suggestion is that pharmacological treatment of PTSD with the selective serotonin reuptake inhibitors (SSRI), paroxetine has reported to increase hippocampus volume. Thus, reduced hippocampus volume could be an acquired reversible abnormality even as it is a preexisting risk factors.

Functional Neuroimaging Studies

Functional imaging studies using positron emission tomography or functional MRI (fMRI) have shown many activity changes in the brain of people with PTSD. The amygdala is involved in recognizing stimuli signaling danger and the fear response and has exaggerated activities in individuals with PTSD. In contrast, activities of the ventromedial prefrontal cortex (VMPC) are reduced. The VMPC reduces the fear response and its activity and is negatively correlated with PTSD symptoms. The inactivity of VMPC and the continued exaggerated amygdala response may indicate why extinction does not occur in PTSD patients.

Much research has found that cortisol is either reduced or normal in individuals with PTSD and as not as high as expected when in a state of chronic stress. Cortisol is a hormone, released from the adrenal cortex in an acute response to stress in a threatening or uncontrollable nature. The concept of cortisol deficiency in the pathogenesis of PTSD is supported by a preliminary study of high-dose cortisol administration. The study showed that administration of cortisol within hours of a traumatic event reduced the development of PTSD.

Neuroendocrine Studies

There is much evidence of the sympathetic nervous system hyperactivity adrenergic response (adrenaline or norepinephrine) in PTSD. An increase of norepinephrine may influence a formation of durable traumatic memories. It also contributes of hyperarousal symptoms including nightmares, flashbacks, intrusive memories, and a physiological response to traumatic stimuli. The efficacy of prazosin and clonidine, central nervous system blocking agents, in treating hyperarousal symptoms are consistent with these findings (Boehnlein and Kinzie, 2007).

Neurobiological Research

This brief summary of emerging and increasingly sophisticated studies of the neurobiology involved in PTSD has shown robust findings with contradicting results. They do point out that there are several clear biological mechanism involved in the brain during severe trauma and are hopeful that further research will lead to more definitive treatments. Neurobiological research has helped to elucidate basic mechanism of PTSD and lead to rational understanding of the psychological therapies as well as pharmacological treatments.

Psychological Treatment

Psychological interventions are widely used in the treatment of PTSD; an analysis of types of intervention include trauma-focused cognitive behavior therapies, exposure therapies, stress management, and eye movement desensitization and reprocessing . An early report indicated that there is evidence for the effectiveness of all these treatment of people with PTSD (Bisson and Andrew, 2007). Nontrauma-focused therapies did not reduce PTSD symptoms as significantly as trauma-focused therapies. More recently, it has suggested that prolonged exposure therapy (PET) as a first line treatment for PTSD has been demonstrated to reduce comorbid issues such as anger, guilt, and depression, in diagnostically complex population. The main components are psychological education, prolonged imaginative exposure, and emotional reprocessing. These have been supported by the American Veteran's Health Administration for training of mental health professionals (Rauch et al., 2012). In a comparison of exposure versus cognitive therapy, it was found there were no significant differences in the relative effectiveness of the two in PTSD (Ougrin, 2011). It has been universally accepted concept that trauma-focused therapies are superior to nontrauma-focused therapies for PTSD. However, there is now evidence that this may not be true. The results may be influenced by a selection bias and not controlling for nonspecific or common factors. It may that suggests that nontrauma-focused intervention may be just as effective (Wempolda et al., 2010). A nontrauma-focused therapy called present-centered therapy was originally designed as a control treatment but is now listed as a research-supported intervention for people with PTSD. There is a point of research to see if trauma-focused interventions are necessary for treating PTSD (Imel et al., 2012).

Clearly, the amount of severe trauma presented by PTSD patients strains the therapist's ability as well as the treatment paradigm in delivering psychotherapy for people with PTSD. Complex and atypical patients such as survivors of child abuse or severe trauma like concentration camps require a more modified approach than the often protocol indicated from research design. There is a need for therapist flexibility and deviation from the usual treatment approaches. Clear cases are traumatized refugees who have undergone severe trauma as well as multiple losses, perhaps over a long period of time. An important ingredient in successful treatment may be the nonspecific factors such as the establishment of trust, a good relationship with the therapist, and the professional's compassion in working with these difficult patients (Mirdel et al., 2012; Kinzie, 2001). The nonspecific factors have relevance for the Western-traumatized patients where previously specific techniques have been emphasized.

Combined Medicine and Psychotherapy

A recent article using PET and paroxetine SSRI for PTSD-related symptoms to the World Trade Center attack found that the combination therapy resulted in significant improvement compared to placebo in both response rate and quality of life (Schneier et al., 2012). In combined supportive psychotherapy with medicine proved to be very helpful for severely tortured refugees after 1 year of treatment. This was a nontrauma-focused therapy with emphasis on the relationship and treatment consistent with the culture, 20 out of 22 had a good treatment response at 1 year (Kinzie et al., 2013).

Pharmacological Therapy for PTSD

There is a great deal of evidence now that many of the symptoms of PTSD respond to medication. Paroxetine is FDA approved for the treatment of PTSD, but there is little reason to suggest it is better than any other SSRI. Probably the most consistent approach psychiatrists have used is to use targeted agents for specific symptoms of PTSD and their comorbid disorders (Jeffreys et al., 2012). The following suggestions are from Jeffrey's article and from the personal experience of the author treating thousands of patients over 30 years. It is clear that medicine cannot work by themselves and need to be combined with ongoing psychotherapy, either trauma focused or relationship focused such as interpersonal or supportive. Also, the guidelines are only suggestions and that most medicines have side effects and must be individualized to the patient's needs and symptoms. Most pharmacological therapies include SSRI or a combination of serotonin–norepinephrine reuptake, such as venlafaxine. They often are ineffective for nightmares and reexperiencing phenomena. The most common complaints for severe PTSD are poor sleep, nightmares, and intrusive thoughts, to which tricyclic antidepressant such as imipramine or doxepin, which are more sedative, have greater effects on these complaints, and are very helpful. Nightmares and reexperiencing are often helped by prazosin and clonidine (Boehnlein and Kinzie, 2007). Aggressive-agitated behavior is often helped by a low dose of antipsychotic risperdal. The SSRI and tricyclic antidepressants can treat the comorbid MDD. Most medical treatment needs to be long term and can sometimes be overridden by ongoing or renewed trauma. The rapid relief of sleep disorders, nightmares, and aggressions with medication often gives the patient immediate relief and help them to maintain in psychotherapy treatment.

New and Emerging Research

Clonidine, an adrenergic blocking agent in the central nervous system can disrupt fear memory retention. Thus, when administered after retrieval of traumatic memories, it could prevent the reconsolidation and augment exposure therapy (Gamache et al., 2012). An unusual treatment is to use deep trans-cortical magnetic stimulation with brief exposure therapy in PTSD. A study has found that there was significant improvement in the intrusive component of PTSD after deep brain stimulation to the traumatic event script (Isserlei et al., 2013). Other agents involved in PTSD treatment trials include steroids, glutamate, and dopamine, used in combination with exposure therapy for PTSD (Dunlop et al., 2012).

A problem for all PTSD research and research for many psychiatric disorders is that the diagnosis is often made as of result of self-reported symptoms and sometimes clinician's observation. There is no real biomarker that would definitively diagnose and reliably provide objective evidence of PTSD. Such

a long-term study is underway at New York University and they lead to reliable markers for PTSD as well as mild traumatic brain injury (*New York Times,* 7 February 2013, page 18).

Post-Traumatic Stress in Social Work

Orit Nuttman-Shwartz, The Israeli National Council for Social Work, School of Social Work, Sapir College, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Over 60% of all individuals around the world have been exposed to traumatic events. Responses to those events range from pathological symptoms and vulnerability to healthy responses, hardiness, and resilience. These responses derive from individual, family, community, and social resources, as well as from the ability of individuals to cope with the events, and to work through the consequences of their exposure. This article relates to the role of social workers before, during, and after traumatic events. A brief definition and description of the main responses to these situations is provided, followed by a discussion of social workers' approaches and strategies of intervention. Implications for educational and professional training, the cost of care, and for practice are also discussed.

Introduction

Over 60% of all individuals around the world have been exposed to traumatic events such as violence, abuse, terror, civil and political wars, racial strife, human trafficking, forced migration, human immunodeficiency virus/acquired immunodeficiency syndrome, and technological and natural disasters. Traumatic events are private, public, or international, and they significantly affect individuals, families, groups, and communities in a variety of contexts such as the war in Croatia (1991–95), the London bombings (2005), the September 11 terrorist attack (2001), and the Israeli-Palestinian conflict. In addition, many traumatic events have occurred in civilian environments. For example, in the United States there have been the shootings at Virginia Tech University (2007), at a movie theater in Dallas (2012), and at an elementary school in Connecticut (2012). Traumatic events also result from natural disasters such as Hurricane Katrina in New Orleans (2005), the Tsunami in Asia (2004), and the earthquake in Haiti (2010).

In recent years, there has been increasing recognition that individual differences in responses to traumatic events cover a broad spectrum, ranging from pathological to healthy responses and from short-term to long-term responses. They also include the ability to cope, recover, and work through these events, as well as to identify risk and protective factors. Finally, numerous transpersonal factors can contribute to or detract from healthy functioning in the aftermath of such events. These factors combine person-centered variables (e.g., disposition and personality) with sociocontextual variables (e.g., family interaction and community support systems) and risk and protective factors.

These understandings have led to a shift from a medical approach, which focuses on traumatic responses, to a psychosocial approach, which is based on the results of theoretical and empirical research evidence indicating that individual responses to traumatic events are affected by one's subjective perspective of the event. This approach is well known as stress theory (Lazarus and Folkman, 1984). It has also been argued that responses to traumatic events are the result of personal and social resources that enable people to cope with the aftermath of those events, as coined in the Conservation of Resources (COR) theory (Hobfoll et al., 1995).

In addition to the increasing rate of traumatic events, the above understandings have been heightened by the growing identification of social workers with the field of trauma and their need to face unprecedented challenges in responding effectively to their clients' trauma-related experiences. Therefore, this article will relate to the role of social workers before, during, and after traumatic events that result from civil and national traumas as well as from natural disasters. Following a brief definition and description of the main responses, social workers' approaches and methods of intervention in situations of trauma will be discussed. The article will conclude with a critical reflection on the uniqueness of being a social worker dealing with traumatic events in today's world, which is full of violence.

The Ramifications of Trauma

Two seemingly opposing notions relate to the negative ramifications of trauma on the one hand, and positive responses in the immediate and long-term period after traumatic events on the other. The current understanding is that the responses to a potentially traumatic event fall within a spectrum ranging from pathological to salutogenic (healthy) responses, and from vulnerability to resilience on the other.

Pathological Responses

The first notion, which is most prevalent, is based on the assumption that trauma has a pathogenic effect. Traumatic events jeopardize physical and psychological equilibrium, and give rise to a wide range of physical and mental health complications. There is extensive empirical research evidence in support of this view, which has documented increased rates of posttraumatic stress disorder (PTSD), depression, anxiety, somatization, and alcoholism following traumatic events (Dohrenwend et al., 2006). PTSD is one of the most substantial long-term psychopathological sequelae of such distress. Its symptoms can be grouped into three main clusters. The first consists of persistent reexperiencing of the traumatic event, such as recurrent dreams and flashbacks. The second is persistent avoidance of internal or external cues, such as avoiding

thoughts and activities associated with the trauma, diminished interest, detachment, restricted affect, and sense of foreshortened future. Finally, increased arousal is manifested in difficulty sleeping, irritability, difficulty concentrating, hypervigilance, and exaggerated startle responses (American Psychiatric Association, 1994). The core symptoms of PTSD (intrusive images and thoughts, avoidance, and arousal) severely impair day-to-day functioning, and have a significant negative impact on one's intrapersonal and social life. Although over 90% of the exposed population shows acute stress responses immediately after traumatic events, the majority successfully returns to normal routines, and cope remarkably well. Only 5–11% of these individuals have long-term distress effects, and have been diagnosed with PTSD (Bonanno and Mancini, 2012). Although most of the existing literature on trauma and posttraumatic stress focuses on the effects of trauma on the primary survivor, i.e., the person who directly experienced the traumatic event, direct exposure to trauma not only jeopardizes a person's own physical and mental health, but also undermines that person's familial, occupational, and social functioning (Solomon, 1993).

Salutogenic Responses

An alternative perspective proposes that trauma has a salutogenic effect, and that survivors may gain psychological benefits. According to this perspective, which is in line with positive psychology theory, individuals can develop a positive outlook and further experience positive psychological changes in the wake of traumatic events. The commonly held concept of posttraumatic growth (PTG, Tedeschi and Calhoun, 1996) proposes that individuals transform in new ways that go beyond their pretrauma level of psychological functioning. PTG is described as the subjective experience of positive psychological change reported by an individual as a result of coping with trauma. PTG relates to a variety of positive psychological changes, including increased appreciation of life, setting of new life priorities, a sense of increased personal strength, identification of new life possibilities, improved closeness in intimate relationships, appreciation of life, and/or positive spiritual change.

Without underrating the pathogenic impact of trauma, there is growing research evidence of PTG reported by survivors following various physical and psychological traumas. Such outcomes have been documented following a variety of traumatic events, including natural disasters, war, and terror (for a review, see Linley and Joseph, 2004).

Continuing with the Routine and Resiliency

Despite these emotional reactions, many people tend to maintain their usual routines. Several theorists have used the term resilience in reference to the ability to overcome, to recover, and even to cope well with extreme stressors (Bonanno et al., 2011).

The capacity for resilience has been defined as "the ability of human being in otherwise normal circumstances who are exposed to an isolated and potentially highly disruptive event, such as the death of a close relation or a violent or life-threatening situation, to maintain relatively stable, healthy levels of psychological and physical functioning" (Bonanno, 2004: p. 20). Ungar (2008), using a broader psychosocial perspective, defines resilience as "The capacity of individuals to navigate their way to resources that sustain well-being; the capacity of individuals' physical and social ecologies to provide those resources; and the capacity of individuals, their families and communities to negotiate culturally meaningful ways for resources to be shared" (p. 225).

Ungar's definition highlights the importance of considering the broad systems surrounding the individual, such as family, community, nation, and state, as factors that explain the ability to cope with exposure to traumatic events and the society's role in times of crisis (Breckenridge and James, 2010).

This current and broader definition of resilience is in line with stress theory, which focuses on how individuals perceive traumatic events (Lazarus and Folkman, 1984), and with COR theory (Hobfoll, 1989), which is based on the idea that both the availability of resources and the change in resources that often results from highly disruptive events play a crucial role in human adaptability to extreme stress. These resources are economic and material resources (e.g., income and income loss), energy resources (e.g., the availability of health insurance, of money and knowledge), interpersonal resources (e.g., positive and negative interpersonal support, availability of affinity groups), and work resources (e.g., gainful employment or loss of employment).

This concept is also consistent with the 'person-in-environment' approach, which is a prevalent approach in social work, and supports the idea that it is important to interweave social and environmental resources while working with service users (Hare, 2004). Based on this perspective, the social work profession seeks to augment the ability of individuals, families, and communities to solve their problems and realize their potential (Breckenridge and James, 2010).

Trauma and Social Work

In social work, trauma is often defined and subsumed within its impact on microlevel fields of practice such as child protection, family violence, military social work, and social and interpersonal violence. These definitions present social work education with the conceptual and philosophical challenge of aligning concepts of trauma with notions of strength, recovery, and resilience.

Historically, there is a plethora of literature substantiating the importance of responding to individuals who have experienced trauma. More recently, however, there is evidence of a growing recognition emanating from both the disciplinary and interdisciplinary literature regarding the effects of traumatic events on communities (including nations) as well as the importance of community responses to promote well-being and healing among traumatized individuals. Moreover, individuals and communities themselves are more aware of the potential effects of trauma on health and well-being, thus creating a consumer-led demand for appropriate services. In addition, in the mid-twentieth century, social work journals began publishing articles using the crisis intervention framework and

promulgating specialized training of social workers in agencies that work with clients in crises (NASW, 2008).

Simultaneously, social workers have been trained to work with clients experiencing both acute and chronic stress, to intervene before and during crises, and to implement prevention and postintervention services. These services include individual, family, and group interventions aimed at helping trauma victims achieve 'reasonable mastery' and caring relationships after a traumatic event. In addition, today social workers routinely work in the global arena with people who have experienced multiple traumas. As a result, it is essential for social workers and all human service providers to have an understanding of trauma and the range of its possible effects in order to provide effective, multifaceted intervention in health and welfare contexts.

Moreover, in line with its mission, social work aims to promote social justice and well-being for all people, particularly those who are vulnerable, oppressed, marginalized, and live in poverty. The majority of clients that social workers encounter have experienced numerous and diverse traumatic experiences. As a result, trauma intervention has been incorporated as part of the concepts and values of social work. Within this, the Person in Environment (PIE) approach has been used as a basis for training and for intervention with individuals, families, communities, and societies that have experienced trauma (Joseph and Murphy, 2013). Cultural, ethnic, racial, and other socioeconomic differences have been addressed in an attempt to create policies that strengthen people who need to cope with traumatic events, to reduce conflicts and inequity, and to promote reconciliation and social justice.

In this context, social workers and professionals from other disciplines have been increasingly engaging in forms of 'multifaceted intervention,' which both encompass and depart from traditional approaches that focus primarily on individuals. Notably, these more comprehensive responses promote the integration of community development approaches with psychosocial interventions.

Not surprisingly, the use of combined or multifaceted responses has found increasing support in a number of trauma-related fields, including work with refugees, interventions in disaster-affected communities, and interventions in schools affected by youth suicide and violence, as well as interventions with victims of sexual and physical violence. The rapid development of research-informed practice that has occurred in the field of trauma presents a new and immediate challenge for educators: to prepare students and professionals to provide informed multifaceted interventions in their future practice.

Diversity of Client Populations

Besides providing first aid to trauma victims, the first obligation of social workers is to populations served by various social service agencies. These populations include people with physical and mental disabilities, and children and adolescents at risk living in residential out-of-home settings, as well as young people with learning disabilities, older persons in institutional and community settings (state, municipal, and private), and prisoners. These populations are defined as disadvantaged, excluded, and even invisible, and have been referred to as the 'first recipients of assistance' (Lobley, 2007).

The basic assumption is that as results of social structural problems, these populations are at high risk for developing pathological responses following exposure to traumatic events. They have limited environmental and personal resources at their disposal at times of crisis, because they usually rely on assistance from social workers in routine situations. Accordingly, social workers have to help make decisions, such as those regarding the need to evacuate people from danger zones during natural (e.g., hurricane or flooding) or (hu)man-made disasters (e.g., war and terror attacks) and the need to give them access to psychosocial assistance as well as provide life-saving medications, food, water, shelter, and clothing. In addition, social workers provide psychological and emotional assistance to help them cope with danger, exposure to threat, and the consequences of such situations.

The 'second recipients of assistance' refers to populations that are known to social services but are not in active contact with a helping professional at the time of the traumatic event. In this context, social workers have to evaluate the extent to which these individuals and their families need assistance following the traumatic event. It is important to examine whether they require assistance due to the new situation that has arisen, what individual and family support systems are available to them, and what role the community they live in can play in helping them. In emergency situations, social workers have to actively initiate assistance, because they are supposed to have the information about individuals and communities that have been exposed to traumatic event.

The 'third recipients of assistance' refers to the community at large, the region, or the state/nation. In this context, social workers need to make constant, long-term help available in accordance with the nature and scope of the event. Assistance provided at this level includes intervention in acute stress situations as well as identification, mediation, and cooperating with key figures from various disciplines and helping the community return to a daily routine. In addition, before being exposed to the traumatic event, social workers need to initiate policies that facilitate their implementation in situations of crisis and trauma by influencing processes of decision making and policy making. In addition, they need to train the system of psychosocial services before the event so that the procedures for working with the population will be clear. These procedures should be based on pooling community, environmental, and national resources. Moreover, it is no less important to base the procedures on strengthening the community and promoting its resilience during and after the events. In so doing, social workers not only need to be concerned with bringing the community back to a normal routine in terms of physical, social, and emotional functioning and with self-care but also need to worry about themselves. The last circle relates to the trauma workers themselves including social workers as direct and indirect exposure to the traumatic events (see STR subsection below).

Types of Interventions

Social workers deal with trauma among individuals, families, groups, communities, and policy makers while focusing on

interventions aimed at prevention, therapy, and return to routine. For example, they analyze the differences between supportive counseling interventions and interventions that aim to process trauma and reduce symptoms of distress. In relation to the community, social workers highlight the importance of local and informal social and support networks, as well as the role of public acknowledgment of traumatization. Given the nature of their role, they focus mainly on minorities and subculture populations, and deal with the trauma at the levels of ambiguous loss (of country, culture, and place) and real loss (e.g., Atkinson, 2006).

Traditionally, social workers engage in individual direct practice, which is based on a variety of psychological approaches such as crisis intervention, first aid, and narrative therapy. Recently, there has been a shift to behavioral and cognitive therapy techniques such as critical incident stress debriefing, cognitive behavioral therapy, prolonged exposure, and eye movement desensitization and reprocessing (e.g., Lee and Drummond, 2008), and trauma and stress management, which have been found to be more effective than traditional psychodynamic ways of intervention (e.g., Foa et al., 2000). In addition, family child therapy has become more common as a result of the acknowledgment that there is a relationship between parental responses to traumatic events and the responses of children, babies, young people, and adolescents. In the same vein, child–parent therapy that focuses on a behavioral approach has become common (e.g., Fredman et al., 2011).

In light of the increasing prevalence of traumatic events, which have affected a wide range of populations, group intervention methods have become very popular. These interventions range from debriefing groups and short-term interventions to open groups, long-term interventions, and self-help groups. Through the groups, trauma victims can share their stories with their partners or with others who have experienced similar situations (see also Weinberg et al., 2005).

Recently, as part of the strengths-based approach, the multidisciplinary perspective of mindfulness and creative therapy has become more common as a way in which the community/social network facilitates healing and recovery among individuals. In addition, social workers can help individuals and communities engage in social action or legal reform efforts aimed at increasing awareness and exercising rights to security in their unstable situation before or after the traumatic events.

Finally, global issues are illuminated when vulnerable populations in different parts of the world experience natural or technological disasters. In those situations, social workers tend to engage in disaster and crisis management in contexts such as refugee camps, which require cultural sensitivity and relativity (Gray, 1996).

The Trauma Helpers – Secondary Traumatization, Vicarious Traumatization, and Compassion Fatigue

It has been recognized that a traumatic event may also have far-reaching consequences for significant others, especially for family members. A wide range of emotional symptoms has been identified among family members of Holocaust survivors, children of combat soldiers, and therapists working with victims of violence (Dekel and Monson, 2010). The ramifications of working with trauma survivors have been described through a variety of well-known concepts, including vicarious traumatization (Pearlman and MacIan, 1995), compassion fatigue (Figley, 1995), secondary traumatic stress (Stamm, 2002), and burnout (Maslach and Leiter, 1997). Specifically, Figley (1995) proposed the term 'compassion fatigue' to describe the long-term cumulative stress resulting from the 'cost of caring.' He articulated a comprehensive description of the cognitive, emotional, behavioral, spiritual, and somatic symptoms that can manifest themselves in compassion fatigue, as well as ways in which it can negatively influence one's personal relations and work performance. Secondary traumatic stress, by contrast, can occur suddenly and is directly related to the client's experience of trauma rather than to cumulative professional stress per se. Secondary trauma symptoms are akin to those of posttraumatic stress, and involve anxiety, depression, avoidance, and hyperarousal. These symptoms are in response to the client's trauma narrative, and the clinician's reaction may mirror that of the client. Highly empathic and neophyte clinicians are more prone to develop secondary traumatic stress than are seasoned mental health professionals. Vicarious trauma, like secondary traumatic stress, occurs in the context of work with trauma survivors. Unlike secondary traumatic stress, however, it is not considered a pathological process. Rather, emphasis is on the cognitive and emotional transformations that occur as a result of empathic engagement with trauma survivors. As with secondary traumatic stress, these changes are most pronounced among highly empathic and neophyte therapists as well as among clinicians with a previous trauma history. These changes take place in the totality of the therapist's life. They interfere with the therapist's feelings, cognitive schemata, memories, self-esteem, and/or sense of safety, and they include permanent alterations in one's self-concept and worldview. Vicarious trauma is a unique, albeit common consequence of trauma work, and it does not reflect psychopathology in either the therapist or the survivor client (Pearlman and Saakvitne, 1995).

Shared Traumatic Reality

In the wake of the recent increase in acts of terror and natural disasters, both the clinical and research literature have focused more attention on the problems that arise in a situation where both the social worker and the client are exposed to a similar threat, and on the implications of such exposure for the helping professions.

This situation, which has been referred to as *shared* (*traumatic*) *reality* (STR), is defined as the affective, behavioral, cognitive, spiritual, and multimodal responses that clinicians experience as a result of exposure to the same collective trauma as their clients. Like vicarious traumatization, these reactions have the potential to cause permanent alterations in the clinician's existing mental schema and worldview. However, in contrast to vicarious traumatization, the primary experience of shared trauma causes therapists to become potentially more susceptible to posttraumatic stress, as well as to blurring of professional and personal boundaries, and to increased

self-disclosure. Shared trauma symptoms are attributed to the dual nature of the exposure. Findings indicate that under these circumstances, therapists feel that their ability to help is impaired, and they experience heightened work-related stress as a result of greater demands on their professional time, the sense that they are professionally unprepared for the situation, and loss of boundaries between their personal and professional selves (Cronin et al., 2007; Tosone et al., 2012).

The Other Side of the Coin – 'Vicarious Resilience'

Parallel to the PTG process, Hernandez et al. (2007) have also discussed a relatively new concept referred to as 'vicarious resilience' (VR). This concept provides a basis for considering how the stories of trauma survivors may also sustain and empower workers, and is congruent with many of the strengths-based approaches to practice. VR offers a counterbalance to the negative effects of trauma work on therapists. This concept suggests that if the therapists are open to and aware of the possibility and utility of VR, their ability to reframe negative events and coping skills may be enhanced through work with trauma survivors. Research findings have also shown that therapists who succeed in finding new methods of intervention that help both their clients and themselves have reported an increased sense of competence (Bauwens and Tosone, 2010). A supportive environment and a part-time position can also enhance their ability to develop VR in their work with disadvantaged and traumatized populations and in STR situations (Stevenson et al., 2011).

Models of Training for Intervention in Situations of Stress and Trauma

Considering how the experiences of trauma pervade social work practice, there is a growing body of literature on models that have been employed in trauma education. The most common one is the classic model, a theoretical course on the nature and effects of trauma, which provides an essential foundation for helping professionals and students to understand the context in which they operate (Cunningham, 2003). In addition, training workshops that emphasize practical skills have also been developed (Fournier, 2002). Besides providing theoretical knowledge and skills in respect to stress situations, trauma, and PTSD, the workshops also elicit active participation to create a suitable learning environment and fashion the group as an educational-experiential space, which is very common in the social work education process. A third model often used in training social work supervisors places emphasis on creating a supportive group space that aims to help social workers manage stress successfully and reestablish and enhance their confidence in their professional and personal capabilities (Cwikel et al., 1993). This model is of particular value in a shared traumatic reality, where it is essential to combine client-focused training and work with the care providers themselves, who have been exposed to the same anxiety and insecurity.

As a rule, these models have all been employed with professionals. However, studies conducted among students of social work have revealed that the students are especially vulnerable due to lack of suitable training and insufficient knowledge (Cunningham, 2003). Moreover, the students have not yet acquired and internalized stable theoretical foundations for their work, nor have they developed a clear understanding of the meaning of secondary traumatization or adequate coping strategies. In addition, students have been found to display a tendency for isolation, scapegoating, and interpersonal distance (Cunningham, 2004). Thus, social workers as supervisors need to address the issues raised by students and prevent the development of isolation and feelings of being neglected. The social workers need to keep in mind their important role in supporting students, to help them implement emotional self-regulation, offer a containing and holding environment, and legitimate concerns about being less effective while they themselves are exposed to a threat.

Another relevant issue is coping with trauma in a traumatized society, particularly against the background of national conflict and threats to security. This situation also impacts on the dynamic processes that typify helping relationships, as well as on study and supervision groups. As a result, efforts have been made to develop a global curriculum for social work in the context of social and political traumatic events and conflict, and to incorporate this content in professional core knowledge (Duffy et al., 2013).

Summary and Conclusion

Although social work and other disciplines share universal aspects of understanding and responding to the needs of trauma survivors, the perspective of social work is unique, in that it reflects the values of the profession and emphasizes two aspects. First, social work focuses on understanding the development, functioning, challenges, and needs of people and social systems in situations of trauma from a relational viewpoint and within the context of their environments (e.g., immediate and extended family relationships and cultural, social, racial, ethnic, and religious/spiritual affiliation). Second, social work views people and systems through a holistic, multidimensional lens, which addresses individuals, families, groups, and communities from a perspective that recognizes strengths, resilience, and the ability to cope and thrive in addition to challenges, difficulties, and pathologies (Berger, 2012).

In many cases, social workers serve as 'first-aid helpers' who provide assistance immediately after traumatic events, in addition to providing long-term assistance that is similar to the help provided by other professionals. The multidisciplinary approach to trauma is expressed in training provided at social work schools as well as in the establishment of professional organizations and accreditation. The Council on Social Work Education, for example, has recently published a manual for social workers on work in situations of trauma. In addition, there are studies that have highlighted the complexity and difficulty of social work with clients who have experienced traumatic events, including research reports on the implications of working in a shared reality.

Nonetheless, the question arises: How do social workers respond to the unique challenges of their profession, which

combines interventions ranging from prevention and policy making to short- and long-term interventions that focus not only on the microlevel but also on the macrolevel, as well as on promoting growth, strengths, and resilience? Another question is whether the methods and levels of interventions implemented by social workers are consistent with evidence-based practice and cultural sensitivity, and whether they meet the demands of the complex reality preceding traumatic events, and especially following those events. Research findings have shown that more efforts need to be invested in training social workers and providing them with methods for working with clients who have lived through loss, extreme stress, and trauma when they have been exposed to the same traumatic events as those clients.

To conclude, in line with the residual concept of social work, the contribution of trauma intervention by social workers is as follows:

1. *Incorporating the PIE approach before, during, and after the event*: Emphasis should be placed on prevention, provision of responses, returning to a routine, and even creating and promoting sustainability.
2. *Seeing the person and environment as a whole*: Incorporating the positive and strengths-based approaches that have been found to be effective in promoting healing, recovery, health, and well-being as a result of the fact that the majority of the population is resilient and can cope successfully with the traumatic events. As such, the chances of recovery also depend on individuals and their social resources, identity, sense of belonging, and sense of support.
3. *Incorporating culturally sensitive concepts* in the intervention methods used by social workers while responding to traumatic events and providing suitable assistance to minorities, different cultural subgroups, and others.
4. *Implementing interventions at all levels* such as working with policy makers, communities, families, and individuals. This will also help social workers devote time to working with populations at risk and advocating for those who have been referred to as 'invisible populations.'

In the light of the above, future effort is needed to implement evidence-based practice, as well as to expand existing knowledge and update this with biomedical and alternative perspectives. Toward this end, there is a need to incorporate relevant cultural, biological, and historical dimensions of trauma. In addition, social workers in the field of trauma need to address global processes. It is important for social workers to be trained in dealing with international traumas and the social effects of those traumas (e.g., forced relocation and displacement). This work should be based on antioppressive and postcolonial approaches (Marlowe and Adamson, 2011).

Potlatch in Anthropology

ME Harkin, University of Wyoming, Laramie, WY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Potlatch' is a key anthropological concept, which has spread to many other fields of study. It refers to a ceremonial exchange system that arose in the nineteenth century on the Northwest Coast of North America. Although it takes various forms, most attention has been paid to the agonistic displays of the Kwakiutl potlatch.

'Potlatch' is a term, derived from Chinook jargon, used to refer to a variety of exchange practices among aboriginal groups on the Northwest Coast of North America. These practices all involve ceremonial exchange as the central feature, although secondary features, as well as the function and meaning of the exchange, vary considerably from group to group. The concept of 'potlatch' is an anthropological reification of a range of cultural practices characteristic of this area, all of which bear a certain family resemblance, but which cannot be considered a unitary phenomenon. Most discussion of the potlatch focuses on the Kwakiutl (Kwakwaka'wakw) of Vancouver Island, who settled around Fort Rupert in the late nineteenth century and were studied by Franz Boas and his research partner George Hunt. Among the elements stressed by Boas and his followers were agonistic display, balanced reciprocity, loans and repayment with interest, and extreme psychological states. Other scholars, especially those working in the northern region, have stressed themes of cooperation, harmony, and the creation of public meaning. Materialist scholars have stressed the role of the potlatch in spurring economic overproduction or in redistributing resources across microenvironments. The potlatch was outlawed by the Canadian government from 1885 to 1951. However, it persists among many groups in Canada and the United States to this day.

In the broadest sense, 'potlatch' refers to a ceremonial exchange complex of aboriginal peoples of the Northwest Coast of North America. Originating in precontact practices, the potlatch evolved in the nineteenth century into a quasi-commercial system of acquiring prestige through large gifts – and occasionally destruction – of native and trade goods. Among the Kwakiutl and neighboring groups, the potlatch came to include a supplemental economy of loans and interest, allowing for presentations so large that they beggared the host. This extreme form, appearing between roughly 1870 and 1925, earned it a central place in the ethnographic imagination.

History and Origins

Precontact Trade and Ceremonial Exchange

'Potlatch' derives from the Chinook jargon word *patshatl*, to give. Chinook jargon was a trade language centered in the Columbia River basin, but extending north to the central Northwest Coast. It predates European contact and served as a *lingua franca* among groups engaged in aboriginal trade. Archeological evidence suggests the existence of intergroup ceremonial exchange alongside precontact trading relations. However, it is clear that such exchange was both quantitatively and qualitatively different from the historic potlatch. It involved modest amounts of animal pelts and a few types of prestige goods and was known under different labels in different areas. It reaffirmed but likely did not alter rank relations within and between groups. Thus, it is fair to say that the potlatch, as a translocal institution, was a product of the fur trade era.

The Fur Trade: Influx of Wealth

The early fur trade of the 1770s and 1780s involved Russians, Spanish, British, and Americans. Trade focused on the sea otter and was conducted primarily from ships. This had a limited effect on aboriginal groups. However, by the late 1780s, the sheer number of trading vessels, and the shift to land-based trading, had begun to bring changes. The transfer of the Spanish colony on Juan de Fuca Strait to the British in 1793 marked the beginning of a process that would see Hudson's Bay Company forts established all along the coast, and eventually a substantial colony at Victoria. To the north, the Russians established a fort at Sitka, in Tlingit territory, and to the south, Americans established posts on the Columbia River in the 1810s. The shift to land-based trade brought with it an influx of wealth and trade goods, as well as epidemic disease, and a broad range of new cultural influences.

Despite the negative effects of contact, the early nineteenth century was characterized by an efflorescence of art and expressive culture on the Northwest Coast. Nowhere is this seen more clearly than in the plastic arts. The introduction of metal woodworking tools and, somewhat later, commercial paint, allowed for an explosion of art in the form of masks, architectural elements, storage vessels, and free-standing monumental sculpture. Such objects were commissioned with new commercial wealth; these objects, in turn, were vehicles by which this wealth was displayed and validated. Wealth had always been closely associated with rank. The problem arose in that rank was ideologically a closed system: a limited number of ranked positions, associated with titles, privileges, and symbolic property ('crests') were believed to exist, and these positions were filled in accordance with regular principles of descent and succession. However, during the fur trade period, *nouveaux riches* rose to prominence. New crests were created for them by artists who were experimenting with both themes and techniques. Simultaneously, such persons also staked claim to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12135-X

unused traditional crests or those in dispute; given high mortality from a series of epidemics, application of the rules of normal succession (e.g., to nephew or son-in-law) was often impossible. The potlatch was the forum in which such claims were made public and were either validated or rejected by the larger community.

The Dominion Period: Response to Traumatic Change

After the 1860s, which saw both Canadian Dominion and the purchase of Alaska by the United States, aboriginal groups were increasingly encapsulated within Euro-American political, social, and economic institutions. Simultaneously, the full effects of disease mortality were being felt, producing upheavals in aboriginal society. The potlatch, an effective means of dealing with demographic and social change, was mobilized to address issues such as the amalgamation of groups, the lack of personnel to fill important rank positions, changing relations with Euro-Americans, and changes in the relative status of local groups. In the process, potlatches became larger and more expansive. A wide range of aboriginal practices, such as shamanic winter dances, became incorporated within the potlatch. Simultaneously, the potlatch replaced intergroup violence, which was suppressed, as a means for gaining prestige at neighbors' expense.

During this period, the potlatch was suppressed by Canadian authorities, who passed a 'Potlatch Law' in 1885. Although unenforceable for most of its existence, it did result in famous prosecutions and convictions of Kwakiutl potlatchers in 1923. In addition to criminal punishment, the state seized 'potlatch goods,' including ritual objects. These provided the basis of ethnological collections at museums in Ottawa and Toronto. In the 1970s and 1980s, these items were returned to Kwakiutl communities at Cape Mudge and Alert Bay, which have built museums to house them.

Geographical Range and Variation

The Northern Potlatch

The northern region, consisting of matrilineal societies, used the potlatch primarily in the context of funerals and succession. For the Tlingit and Haida, potlatches were between moieties, and stressed cooperation and solidarity between hosts and guests. Moieties, a division of society into two halves, provided an image of social and cosmological totality. In the case of funerals, the opposite moiety provided comfort and assured the reincarnation of the deceased. Nevertheless, a minor theme of competition was often introduced, with two separate guest groups attempting to outdo each other in the degree of 'comfort' provided to the host. To the south, Tsimshian (including Nishga and Gitksan) potlatches were similar, but, lacking moieties, were somewhat more agonistic. They were associated with marriages, as well as other life-crisis rituals; marriage was seen in oppositional terms. In addition, potlatches were used to make territorial claims.

The Southern Potlatch

South of the Tsimshian, social organization was cognatic, with a matrilineal orientation in the north becoming more patrilineal in the south. Among the Nootka (Nuu-chah-nulth), potlatches were essentially private entertainments sponsored by a chief for his people, and thus stressed social harmony. Elsewhere, however, potlatches were primarily agonistic. Marriage potlatches, including those held to repay bridewealth, were often couched in military terms. As group membership and rank were less fixed in cognatic societies, they were more the object of political manipulation, and thus of representation in the potlatch.

The Kwakiutl Potlatch

The extreme example of agonistic prestation was provided by the Kwakiutl, who live on northeastern Vancouver Island and the adjacent islands and mainland. During the 60 years after Dominion, the potlatch intensified to the point that Benedict (1934), in her colorful if flawed analysis of Boas' material (Boas, 1966), described the Kwakiutl as 'megalomaniacal' and 'paranoid.' Fierce competition among brothers, cousins, and affines for succession to titles, the existence of numerous latent titles, the rise of a *nouveaux riche* class called 'Eagles,' and a system of intergroup ranking, all contributed to the intensity of the potlatch, which participants viewed as warfare by other means. Potlatches opened with guests arriving in war regalia, and a mock battle on the beach, reminiscent of the murderous raids that were endemic to this area.

Kwakiutl potlatches were predicated on rivalries between chiefs and, by extension, their groups. In addition to the usual means of amassing wealth, would-be hosts engaged in a system of loans with 100% interest, which allowed lenders to build fortunes quickly and borrowers to obtain last-minute infusions. The currency was Hudson's Bay Company blankets, supplemented and eventually replaced by Canadian currency. Copper shields were the ultimate valuable; bid up in previous transactions, 'coppers' reached cash values of several thousand dollars. In addition, trade goods played an increasing role. By the start of the twentieth century, manufactured items such as shotguns, sewing machines, and pool tables were given away, along with quantities of flour, rice, cloth, and utensils. In some of the most dramatic potlatches, goods including coppers were destroyed.

Functional Accounts

The Potlatch as Total Social Phenomenon

The French sociologist Marcel Mauss (1990) noted that the potlatch is an integral element of the rank system of Northwest Coast societies. It is a mechanism by which claims to rank status are validated or challenged, and changes in social order are communicated to the larger community. The potlatch rests on opposition between host and guest. The host – a chief or high-ranking person and, by extension, his social group – was concerned with conducting certain types of business: naming heirs, contracting marriages, conducting funerals, and proclaiming new titles and privileges. This business was witnessed, in a juridical sense, by the guests, who were paid for their service. Potlatch gifts went beyond mere payment for services, however, since they were also taken as prima facie evidence for the validity of the claim.

Wealth was a necessary concomitant of high rank. High-rank positions implied a certain degree of extraordinary power, similar to the *mana* of Polynesian chiefs, which necessarily resulted in wealth. Inability to provide an abundant potlatch would seriously undermine the legitimacy of the claimant's assertions. By the same token, an extravagant potlatch could 'fasten on' a title, merging the holder's social identity with the permanent qualities of the title. Such acts were seen as a sort of reincarnation, by which the living title holder became incorporated in the title, which encompassed the holder's predecessors and mythical founder. For chiefly positions, the ascendance of a new holder was often marked by events symbolic of the (re)creation of the social world, including human sacrifice, the razing of old chiefly houses and poles, and their replacement by new ones.

In chiefly succession potlatches, a broad range of political, legal, and economic issues were implicated. In all groups, chiefly titles involved territorial claims of some sort. These titles were based on mythical narratives, set locally and taking place at the beginning of human history, thus staking aboriginal claim to land. Among most groups, such territorial claims were very specific and resembled Western notions of ownership. In all Northwest Coast cultures, chiefs were minimally seen as stewards of the land and its inhabitants were responsible for regulating relations between human and nonhuman populations (which were believed to include more than the flora and fauna recognized by biological science). This was accomplished by ritual means, including prayers, attraction magic, and first fruit rituals. The latter were used to regulate the seasons on fish and game. Although the informing ideology was moral, such regulation had the effect of conserving and managing resources in a sustainable manner.

The potlatch thus involved relations between the social group and the nonhuman outside world, the prehuman myth world, and the group's ancestors. In this way, the group was situated within a larger universe and was thus defined and delimited. Potlatches likewise served to delineate the internal organization of society and the functional relations obtaining between its components. In a general sense, one potlatches to one's affines, who constitute the friendly other. In northern matrilineal groups, this opposition was absolutely clear. Especially in the moiety system of the Tlingit and Haida, one's affines were a separate corporate group; the cooperation of the two sides presented an image of social totality cosmological in scope.

The Potlatch and Marriage Exchange

Potlatches were associated with marriage in most areas; even where they were not, the potlatch was transacted between affines. Politically, potlatches were vital in renewing alliances among groups. Among the northern groups, whose aristocrats practiced preferential cross-cousin marriage, long-term stable exchange relations involving two or more local groups were established. Such groups provided political, military, and economic support, as well as external validation of chiefly claims. Among cognatic groups, no such long-term structural relations existed but were rather produced and reproduced in a series of exchanges tied to specific marriages (payment and repayment of bridewealth, naming of children, and funeral of a spouse). The connection between marriage and potlatching was so strong that in groups such as the Kwakiutl, Bella Coola, and Heiltsuk, aristocrats would engage in serial monogamy and even fictive marriage in order to obtain prestige from potlatching. Potlatching varied along several dimensions (size, number, occasion, agonism, and others) depending on the precise configuration of kinship, descent, and marriage rules. Among the Kwakiutl and neighboring groups, marriage was viewed as a limited contract. The repayment of the bridewealth (often many times over) in a potlatch by the wife's natal family effectively ended that contract. For aristocratic women (nonnobles were said not to marry at all, since they did not potlatch), a typical career involved marrying multiple times.

Potlatching is a profoundly gendered institution. It is a prototypical masculine activity (along with fishing, hunting, and warfare). Men derive both tangible and intangible (but culturally highly important) property, as well as prestige and political power. Women gain as well, but can be viewed as another class of object exchanged among men. Indeed, Lévi-Strauss's notion of the circulation of women and property between groups has been shown by Rosman and Rubel to have considerable relevance to Northwest Coast ethnology (Rosman and Rubel, 1971). At the same time, women are consciously advancing their own careers. While not eligible for chiefly titles, they nevertheless were said to become more 'heavy' with successive potlatches. Heaviness is the archetypal quality of aristocrats; they are seen as more 'real' than others. Heaviness is symbolically associated with copper, the form and symbol of wealth in traditional Northwest Coast cultures. As women were married or had their bridewealth repaid, they were said to be 'heavy with wealth.' This was (and still is) symbolized by the sewing of wealth items, including Canadian currency, into the dress worn by a bride.

The Potlatch and Ecological Variation

Since the 1960s, materialist scholars have viewed the potlatch as a virtual homeostatic mechanism, distributing personnel and food efficiently through space and time. The earlier conception of the Northwest Coast as free from food pressures is justly rejected. The potlatch is seen as having four distinct but interrelated functions: (1) spurring overproduction, (2) encouraging storage of food, (3) allowing for the exchange of food for prestige goods, and (4) regulating group membership and territorial boundaries, matching resources with personnel. This approach assumes local variation in resources, a condition that does not exist everywhere but is more pronounced in the north. Item (4) was affected more often by warfare than by potlatching. However, these remain at least potential functions of the potlatch. More recently, scholars have examined the ways in which potlatching, especially in its more cooperative versions, shared resources, and hence an interest in preserving those resources, among different groups, thus enhancing the sustainability of the fisheries (Trosper, 2009).

Rank, Class, and Political Power

Northwest Coast society was stratified by both rank and class. Potlatching was the domain of chiefs and nobles; however, both commoners and slaves played important roles in amassing resources. By definition, only persons with titles were in

a position to potlatch. Potlatching thus reinforced vertical, as well as horizontal, social divisions. Simultaneously, potlatching was the mechanism by which social mobility was integrated into the social system.

The potlatch both manifested and represented political power. By drawing together a large number of guests, especially if they were from far away or their chiefs were especially high ranking, a host was demonstrating his prestige and the size of his political network. The material goods and food distributed were an index of his land holdings and their productivity, which ultimately depended upon the chief's legitimacy. Potlatches were fora for authoritative political discourse, defined technically as monologic, multichannel, redundant communication. A significant aspect of this communication was an illocutionary speech act. This was supplemented with nonverbal media, including plastic arts and dance. The political success of a potlatch was usually measured in terms of the degree to which these utterances remained unchallenged. They may be challenged directly, in rivalry gestures, or more subtly through various sorts of corrosive discourse, including humor. However, in some groups, such as the Kwakiutl, such elements were institutionalized within the structure of the potlatch. This had the effect of heightening tensions within the potlatch and giving it a more gamelike structure, in which a wide range of outcomes was possible.

These agonistic aspects of the potlatch especially in its Kwakiutl version have drawn the attention of anthropologists and scholars outside the region, making it one of the most famous examples from the anthropological literature. Generosity so great as to be unreciprocable, the symbolic violence of giving on this scale, the destruction of property in dramatic action, the humiliation of rivals: these features have made it a sort of logical limit case and hence useful in theoretical argument. For this reason, David Graeber has employed it to represent the pole of nonreciprocal exchange, which he sees as the origin of money and of modern political power (Graeber, 2001). In this case, logical clarity is purchased at the price of ethnographic veracity. Even among the Kwakiutl of the era of the classic potlatch, various modalities of exchange were employed to a variety of social, political, and religious ends.

Problems of Reference

Reification

Given the degree of variation over space and time, it is unclear that one can say that the potlatch, *as such*, exists. Rather, the understanding of it is conditioned by reifications imposed by government agents and missionaries, anthropologists, and aboriginal people themselves. The Potlatch Law of 1885 first tried to specify "the Indian festival known as the 'Potlatch.'' Problems of reference significantly impeded successful prosecution of the law. During this intervening time, the symbolic labor of many people served to bring descriptions and practice closer together.

Invention of Tradition

Aboriginal people themselves reified the potlatch by defining their ceremonial praxis as potlatch, a foreign word and concept mediated through Euro-American society. By the time Franz Boas recorded ethnographic data among the Kwakiutl in the 1890s (Boas, 1966), the concept of potlatch was present. This consciousness of 'the potlatch,' on the part of both Boas and the Kwakiutl, was shaped largely by the existence of the Potlatch Law. Clearly, aboriginal practice and self-awareness of practice were conditioned by exogenous expectations and categories. It is not surprising that during a period of rapid change such an invention of tradition would occur. It allowed aboriginals to retain symbolic control of their destiny, by redefining novel structures and practices as traditional. Because of this useful quality, potlatching remains a common practice today.

The Potlatch as Anthropological Totem

The potlatch remains one of the most durable anthropological concepts, despite the reanalyses and deconstructions to which it has been subjected. Beginning with Boas, anthropologists defined potlatch as both self and other, transparent and exotic. This contradictory and mediational quality has made potlatch an especially useful metaphorical vehicle. Potlatch has been viewed as, inter alia, metaphorical banking, warfare, and mental illness (Benedict, 1934; Boas, 1966; Codere, 1950). At the same time, various aspects of Western societies, including politics and consumer capitalism, have been compared to potlatch. Its hybrid nature and its origins in the desire on the part of Euro-Americans to describe indigenous peoples, and indigenous peoples to represent change and continuity, make it an attractive concept, but one that resists critical usage.

Abstract

The 'culture of poverty' is a concept popularized by the anthropologist Oscar Lewis during the 1960s in his best-selling ethnographic realist books on family life among the urban poor. Drawing from Freudian culture and personality theory, which dominated US anthropology in the post-World War II period, Lewis listed over 50 traits that he claimed were shared by approximately 20% of the poor, including 'orality,' 'strong present-time orientation,' and a 'high tolerance for psychological pathology.' These traits were said to be transmitted cross-generationally within families and prevented individuals from taking advantage of economic opportunities. Despite Lewis's social democratic politics, his culture of poverty concept resonated with the moralistic condemnation of the unworthy poor deeply ingrained in US popular ideology. It spawned a polemical response from social scientists who criticized its blame-the-victim and psychological reductionist implications. Lewis himself was not concerned with theory, and did not particularly believe that his ethnographic work documented the culture of poverty. The vituperative debates during the 1970s through to the 1990s over whether or not a culture of poverty really exists were not fruitful theoretically. They tend to degenerate into political name calling or into an empirical denial of the lived experience of social suffering among the persistently poor. The uses and misuses of the culture of poverty illustrate how research on social inequality reflects societal biases. They also demonstrate the inadequacy of the culture concept when it is used to explain hierarchy in an essentializing, atheoretical vacuum that ignores history and structural power dynamics.

The culture of poverty concept was developed in the USA during the 1960s primarily through the best- selling ethnographic realist publications of the cultural anthropologist Oscar Lewis, who tape-recorded eloquent life histories of the urban poor. He reprinted numerous versions of his definition of the term 'culture of poverty' in short journal articles and also in the introductions to his books on family life among Mexicans, Puerto Ricans, and Cubans living in shanty towns and ghettos (Lewis, 1961, 1966a,b, 1967). Lewis's culture of poverty struck an academic identity politics nerve, and at the turn of the millennium the concept remained enmired in a bitter polemic over how to analyze and engage politically the persistence of poverty in the midst of postindustrial plenty.

Ideological Backdrop to the Culture of Poverty

In the USA, irrespective of the theoretical orientation of researchers, most discussions on poverty polarize around value judgments concerning individual self-worth or around racial/ethnic stereotypes. US attitudes towards poverty are rooted in the country's colonial Calvinist/Puritanical heritage and are exacerbated by the historical importance of racialized hierarchies that have legitimized genocide, slavery, colonization, and immigration control. This helps explain why the culture of poverty concept continues to generate so much emotional heat while shedding so little conceptual light. The uses and misuses of the concept offer a fascinating case study in the sociology of knowledge illustrating the political interfaces between theory, empiricism, art, and ethnocentric moralizing in the social sciences.

Poverty research throughout history has been more successful at reflecting the biases of an investigator's society than at analyzing the experience of poverty. The state of poverty research in any given country emerges almost as a litmus for gauging contemporary social attitudes toward inequality and marginaliz- ation. For example, while Lewis's books are read by a US public as an individualistic interpretation of the persistence of poverty that blames victims, in France his work is interpreted as a critique of society's failure to remedy the injuries of class-based inequality under free market capitalism.

Defining the Culture of Poverty

The socialist sociologist Michael Harrington was the first prominent academic to use the phrase 'culture of poverty' in a major publication. His book, *The Other America*, documented rural poverty in Appalachia and represented a moral call to action that anticipated the War on Poverty initiated by President Johnson in 1964 (Harrington, 1962). As a first-generation son of impoverished Jewish immigrants who was influenced by Marxism in his youth, Lewis shared Harrington's social democratic commitment to combating poverty (Rigdon, 1988; Harvey and Reed, 1996). Ironically, however, Lewis's popularization of the culture of poverty concept is said to have tolled an intellectual death knell to the optimistic idealism of the mid-1960s that advocated eradicating poverty through direct state intervention (Katz, 1989). This is because Lewis's definition of the culture of poverty stressed that a significant minority of the poor (approximately 20%) were trapped in self-perpetuating cycles of dysfunctional behaviors and attitudes: 'By the time slum children are age six or seven they have usually absorbed the basic values and attitudes of their subculture and are not psychologically geared to take full advantage of changing conditions or increased opportunities' (Lewis, 1965a: p. xlv).

This kind of psychological reductionist and individualistic interpretation of the persistence of poverty resonated with US popular blame-the-victim discourse. Ironically, in the same articles or book introductions in which he defined the culture of poverty, Lewis also included radical political statements

contradictory to the implication that poverty is caused by self-perpetuating deficient value systems. For example, in his *Scientific American* version of 'The Culture of Poverty' he quotes Frantz Fanon, praises Castro's Cuba, and criticizes 'free-enterprise, pre-welfare-state stage capitalism' for spawning the culture of poverty (Lewis, 1966b). At the same time he states that 'it is much more difficult to undo the culture of poverty than to cure poverty itself,' and advocates 'psychiatric treatment' for poverty in the USA (Lewis, 1966b: p. 25).

In other words, the culture of poverty concept was confused theoretically at its inception. Unfortunately, Lewis never managed to clarify what he intended to mean. His published correspondence reveals that he was profoundly disturbed by the blame-the-victim interpretation of the causes of poverty that he triggered in the USA: 'There is nothing in the concept that puts the onus of poverty on the character of the poor' (Lewis, 1967: p. 499).

The notion of a culture of poverty, consequently, should not be treated as a full-blown theory. As presented by Lewis, it was merely a bundle of some 70 traits which he did not link to a particular processual or dynamic logic. In fact, he never even listed all 70 of the traits that he claimed existed. The theoretical sloppiness of the culture of poverty concept may well be a product of the McCarthyist anticommunism in US academia that impinged on Lewis during his formative years in the 1950s. Four decades after their inception, his lists of culture of poverty character traits appear embarrassingly arbitrary, ethnocentric, and psychologically reductionist (Lewis, 1966a: p. xlviii):

> … a high incidence of maternal deprivation, of orality, of weak ego structure, confusion of sexual identification, a lack of impulse control, a strong present-time orientation with relatively little ability to defer gratification and to plan for the future, a sense of resignation and fatalism … male superiority, and a high tolerance for psychological pathology of all sorts.

The Policy Implications of the Culture of Poverty

In the late 1960s and 1970s Lewis's culture of poverty concept produced an outpouring of political and academic reactions, primarily in the USA but also in Mexico and Puerto Rico (Leacock, 1971; *Alteridades*, 1994). Despite conceiving of his work as a call for the expansion of public-sector intervention on behalf of the poor, his concept took the popular intellectual spotlight off the need for structural economic reform, and glossed over the social power dynamics revolving around class, ethnic, gender, and colonial inequalities. Policy makers, if they paid any attention to the culture of poverty concept, interpreted it as advocating the need to rehabilitate the deficient cultural value systems of poor children through the agency of psychiatric social workers. For example, in the applied policy realm Lewis consulted in the development of the Head Start Program in the USA (Rigdon, 1988), which has been criticized retrospectively as an attempt to 'take inner-city preschoolers who live in lead-painted, rat- infested tenements without steady heat or hot water, and metamorphose them into bright-eyed, upper-middle-class overachievers' (Bourgois, 1995: p. 325). Significantly, in the year 2001, Head Start was still identified by both liberals and conservatives as one of the only successful anti-poverty programs of the 1960s.

The Theoretical Implications of the Culture of Poverty

Unfortunately, most of the hostile academic responses to Lewis's culture of poverty concept have limited themselves to contradicting Lewis's empirical assertions, rather than to critiquing theoretically his psychological reductionism, his sloppy use of the culture concept, and his failure to link in a dynamic manner macrostructural political and economic forces – including gender power relations – to ideology, culture, and individual values (Valentine, 1968; Stack, 1974; for a political economy exception, see Katz, 1989; for a feminist literary criticism exception, see Franco, 1989). The bulk of the negative reaction hinges on a political concern for replacing the negative imagery of Lewis's painful but expressive ethnographic portraits of the everyday suffering of urbanized families, with positive images of the worthy poor, struggling for upward mobility against all odds. A late 1990s rehabilitating of the culture of poverty concept from a Marxist perspective dismissed the virulence of the US progressive reaction against the culture of poverty concept as a sectarian 'ultra Bolshevism' that swept the New Left when the general public was drifting ideologically to the Right following the War on Poverty. This precipitated a 'fruitless game of radical one-upmanship' among frustrated intellectuals, who were completely marginal to public political discourse, and who chose instead to devote their energies to proving their dedication to protecting the image of the poor (Harvey and Reed, 1996). More importantly, the urgent righteousness of the anti-culture of poverty social science literature is comparable to the polemics against Moynihan's 1967 patriarchal attribution of the 'tangle of pathology' in the black family as being the central cause for the persistence of poverty among urban African-Americans (Rainwater and Yancey, 1967).

The angry denial by academics of the existence of the types of violence and self-destructive behaviors described ethnographically by Lewis among the vulnerable families that he tape-recorded and described reveals how far removed intellectuals can be from the inner-city street. Although Lewis's writing deserves criticism for presenting his subjects in a decontextualized pornography of violence, sexuality, and emotional brutality, none of the behaviors or personalities described by Lewis should shock anyone who is familiar with everyday life in the US inner city or Latin-American shanty towns. On the contrary, Lewis's ethnographic realist descriptions, unfortunately, still ring true four decades after they were written. His disturbing material, however, demands theoretical explanation and political contextualization, and that is where both Lewis and his critics and admirers have largely failed. By confining the debate to a worthy versus unworthy poor dichotomy, the internecine squabbles between leftist, liberal, and conservative academics mimetically reproduce the right-wing hegemony in popular US culture that equates poverty with sinfulness.

Arguably, the polemics of righteousness that the culture of poverty prompted scared a generation of social scientists away from ethnographic analyses of inner-city poverty in the USA and, to a lesser extent, around the world (Wilson, 1987: pp. 13–16).

Indeed, accusations of supporting a 'culture of poverty interpretation' are still frequently invoked in polemical identity politics attacks between academics over any representation of poverty that is not flattering to poverty's victims (cf Lassalle and O'Dougherty, 1997). Hence the virulence of the 'underclass debate' in sociology spawned by William Julius Wilson's book *The Truly Disadvantaged* during the late 1980s through the 1990s (Katz, 1989; Wacquant, 1997).

From a theoretical perspective, the legacy of the culture ofpoverty debate has impoverished research in the social sciences on the phenomenon of social suffering, everyday violence, and the intimate experience of structural oppression in industrialized nations. Most importantly, by remaining mired in debates driven by identity politics, researchers have minimized the painful experience of day-to-day survival among the persistently poor. Epidemiological data on the associations between social class interpersonal violence, domestic violence, health outcomes, education outcomes, substance abuse, etc. are simply ignored by most poverty researchers in the USA.

The vacuum of critical intellectual engagement with the phenomenological experience of poverty has allowed right-wing academics subscribing to facile neoliberal blame-the-victim interpretations to capture popular imagination and policy debates – especially in the USA. Social or cultural reproduction theory, which emerged out of studies of poor youth at the intersection of the disciplines of education, sociology, and anthropology during the 1980s and early 1990s, offered a critical theoretical alternative. By focusing on the power dynamics ofthe interface between culture and social inequality, social/cultural reproduction theorists address the empirical reality of the existence of patterns of interpersonal self-destruction without obscuring structural political forces. Although vulnerable to critique for being overly functionalist, these theories allow for the reinscription of agency among the poor, as well as an autonomous role for culture in political economy (Bourdieu and Passeron, 1977; Willis, 1981).

Few serious social science researchers, if any, at the dawn of the twenty-first century would dare utilize the term 'culture of poverty' in their analysis, despite the fact that their empirical and theoretical work addresses cultural expressions of social suffering due to the entrenchment of urban poverty in industrialized and postindustrialized societies. The problematic analytical and political utility of the culture of poverty concept demonstrates how dangerously essentializing the phrase 'culture of …' can become with respect to any concept. Indeed, anthropologists cannot agree upon a useful definition for culture; nor do they understand how it operates without turning it into a black box of totalizing essences (Gupta and Ferguson, 1997).

The culture of poverty furore reminds us that academics fight so hard over so little especially when marginalized political perspectives are at stake. At the turn of the millennium, much of the world's population survives precariously in shanty towns, housing projects, tenements, and homeless encampments where mind-numbing, bone-crushing experiences of poverty engulf the socially vulnerable. Meanwhile, concerned academics continue to fiddle in their ivory towers, arguing over how to talk correctly about the structural violence of poverty.

Abstract

This article examines themes in geographical research on poverty. Given the highly contested nature of the term, I begin with an overview of debates about definitions of poverty. This discussion contrasts absolute and relative poverty measures and critically assesses some of the assumptions embedded with dominant poverty definitions. Next, the article considers the place of geographic research on poverty in critical development studies, emphasizing how the idea of poverty has been fundamental to projects of development. The article then charts shifts in poverty dynamics associated with economic restructuring and welfare reform in the United States. Finally, I analyze the discursive construction of poverty and consider how ideas about poverty categorize and differentiate impoverished places and the poor.

Poverty remains one of the world's most pressing challenges. It is also the subject of intense debate and controversy that reveals a great deal about political economic dynamics, culture, and society. Extremes of wealth and poverty across the globe underlie conditions of health and illness, educational opportunity and illiteracy, land ownership and forced migrations, and employment protections or unregulated 'flexible' work. In spite of numerous agendas to eradicate poverty at various geographic scales over the past century, global poverty remains entrenched and billions of people continue to live in poverty. The World Bank reports that 1.3 billion people were living on less that $1.25 per day in 2008. In the United States, the 2010 Census reports poverty rates at 15.3%, which is an 18-year high (U.S. Census Bureau, 2011). Given these trends, it is perhaps not surprising that poverty remains a prominent focus within governmental policies and in the agendas of international institutions and nongovernmental organizations. The World Bank, for example, now operates under the slogan 'working for a world free of poverty' (www.worldbank.org) and the United Nation's Millennium Goals declare a commitment to ending extreme poverty by 2015 (http://www.un.org/millenniumgoals/poverty.shtml).

Geographic research has been key in demonstrating the highly uneven social and spatial distribution of poverty. At the global scale, the vast majority of the poor live in so-called 'developing nations'. A growing number of the world's poor live in cities. Rapid urbanization resulting from neoliberal policies that have reoriented previously more rural and agrarian economies has contributed to the rise of informal urban settlements and a deepening of urban poverty in the global South. The urbanization of poverty, however, exhibits regional variation. For example, in Central Asia and in Eastern Europe, poverty has deepened in rural areas, while in Latin America poverty in urban areas has intensified (Ravallian et al., 2007). Poverty is distinctly patterned in the United States and the United Kingdom. In the US, poverty rates are differentiated across cities (14.6%), suburbs (11.4%), and rural areas (16.5%) and there is a clear regional trend, with deeply entrenched poverty in areas of the South, Appalachia, the US–Mexico border, and on Native American reservations (Glasmeier, 2006; Kodras, 1997). In the UK, poverty is markedly higher in urban areas and has a clear North–South dimension, with more pronounced poverty in the North and lower rates of poverty in the South (Milbourne, 2010: pp. 161–162). Poverty is highly racialized, with communities of color and racial and ethnic minorities experiencing markedly higher rates of poverty across the globe. Significantly, women of all ages and from all racial and ethnic groups are far more likely to live in poverty than are their male counterparts, a phenomenon that is known as the 'feminization of poverty' (see Pearce, 1978).

Yet many critical human geographers contend that poverty is much more than a statistical measurement mapped onto particular places, arguing that it is better conceptualized as a lived experience shaped by both social and spatial relations. From this position, a reliance exclusively on poverty estimations in specific spatial units constructs poverty subjects and impoverished places in ways that can flatten and homogenize the diverse experiences of the poor and the multifaceted dimensions of poverty in a range of places. As Milbourne (2010) notes, a potential oversight emerging from a focus on statistical measurements is an emphasis on "spatial concentrations of poor people in particular (inner-city) places" and a minimization of "the presence of poverty in other (urban and rural) spaces" (2010: p. 161). Furthermore, these techniques have a tendency to emphasize spatial expressions and distributions of the poor rather than the actual *processes* producing poverty (Milbourne, 2010: p. 161; Lawson, 2012; Kodras, 1997).

Defining and Measuring Poverty

Poverty remains a widely contested and difficult concept to define. Conceptualized as a lack of access to essential basic needs and material goods, poverty is measure of economic health defined through various income thresholds designating the financial means necessary to support households of a particular size and composition (Glasmeier, 2006). Accordingly, the poverty rate is the percentage of the population with income levels lower than the poverty threshold. Poverty thresholds are absolute in that they are a standard applied across social, economic, and spatial contexts.

Increasingly, the efficacy of absolute poverty measures has been called into question. In particular, poverty researchers and policymakers have criticized the rigidity of absolute poverty measures in defining subsistence income levels. These challenges are founded on the basis that poverty varies across places and across time. For example, in the United States, while the absolute number of people in poverty in 1960 was higher (about 20%) than contemporary figures (15.2%), "a poor family today is much worse off compared to an average family than a poor family was in 1960" (Glasmeier, 2006: p. iv). That is to say, although the poverty rate itself has improved, the gap in incomes between an average poor family and an average middle-class family is much wider today than it was in 1960 (Glasmeier, 2006). Additionally, geographic differentiation means that what constitutes poverty and how poverty is experienced can differ dramatically across places. Factors such as local social and economic structures, cost of living differences, and access to public assistance and transportation systems all have the potential to shape the place-specific dynamics of poverty. Absolute poverty measures, however, do not take these geographic distinctions into account.

Another criticism of dominant measures of poverty centers on the way in which subsistence costs for the average family are conceptualized. In U.S. Census poverty measures, for instance, these costs are based upon an assumed 'basket of goods', originally conceptualized by the federal government in the 1960s (Glasmeier, 2006). This hypothetical 'basket of goods' has been contested for resting on outdated assumptions about family costs while minimizing or excluding expenses essential for contemporary household subsistence. For example, when this bundle of goods originated, it was presumed that families spent about one-third of their household income on food (Glasmeier, 2006) whereas today, food consumes much less than one-third of family income. Other expenses like housing, transportation, and healthcare now make up a significant portion of household expenditures but are minimized within Census definitions. Importantly, childcare, which comprises a significant and growing cost for households, is entirely excluded from census-defined 'basket of goods' (Glasmeier, 2006). Feminist critics argue that this conceptualization rests on a highly gendered household ideal comprised of a male breadwinner and a female family caretaker. This critique suggests that 'basket of goods' estimates do not reflect contemporary social and economic realities, namely the rise of – and growing necessity for – dual-income households, a shift that is further underscored by the decline of high-wage, manufacturing employment, and the rise of single-parent, female-headed households.

Taken together, these challenges lead some to suggest that poverty thresholds have the potential to significantly undercount the poor, which, in turn, has far-reaching implications. Federal poverty calculations shape policy responses and the flow of scare resources to low-income communities and programs for the poor. In the United States, these income thresholds unambiguously define who is and is not able to access public services, including critical housing and food supports. In addition, stark income-based definitions fail to account for growing numbers of the 'working poor', or employed individuals earning incomes slightly above the poverty line (see Shipler, 2004).

Some poverty experts advocate using relative rather than absolute poverty measures in order to account for some of these dynamics. Relative poverty defines poverty in relation to median income, rather than as a fixed level of money (Milbourne, 2010; Glasmeier, 2006). For example, in Great Britain, all households with income levels falling below 60% of median income are defined as poor. However, poverty measures based on income thresholds remain widely utilized as a means to count the poor. Calculating poverty through income guidelines allows for standard measures to be made across locations and time periods, facilitating historical comparison and the evaluation spatial patterns. Income-based, absolute poverty measures are therefore useful for broad-scale analysis, and their availability from governmental sources make them accessible for analysis. Nonetheless, interest is growing in alternative measures of poverty, including relative and 'living wage' measures, better suited for capturing geographic variation, new income demands, and the lived experience of poverty.

Geographic Conceptualizations of Poverty

While social inequality has long been of interest to geographers, poverty has been relatively marginalized in human geography compared to other social sciences such as sociology and anthropology. While not excluded from research, poverty has often been folded in with other concepts, such as inequality, deprivation, and welfare in scholarship on socioeconomic inequity and uneven development. Moreover, a bifurcation exists in geographic research on poverty between, on one hand, development scholarship theorizing the poverty in the global South as produced through uneven capital accumulation, unequal trade policies, and development interventions; and, on the other hand, poverty in the global North (especially the US and the UK) in relation to urban and rural restructuring and the reworking of national welfare systems. I reproduce this dichotomy here by separating the discussion of poverty research in the United States from the consideration of poverty and development. However, a burgeoning body of literature in geography theorizes poverty across this divide to connect processes producing poverty in the both the West and the so-called 'developing' world (e.g., Lawson, 2007, 2012; Roy, 2010).

Global Poverty and Development

Much of the research in geography on poverty has emphasized its systemic production through political economic relations. This scholarship connects poverty to the imperatives of capitalism and its attendant dynamics of uneven development and exploitation. These themes are particularly apparent in Marxian development geography, which has focused on poverty in the global South as emerging from histories of imperialism, colonization, and unequal access to power and resources with the global economic system. Geographic scholarship in critical development studies challenges conceptualizations that explain poverty in 'Third World' nations as an outcome of stalled economic progress, physical geography (i.e., the absence of resource endowments), and conflict (Lawson, 2007).

Instead, this research situates poverty as an outcome of historically unequal political economic relationships established through colonization and sustained through contemporary divisions of labor, development interventions, and international trade policy. These studies, therefore, emphasize poverty in relation to exploitation and structural transformations in economy.

Scholarship in this vein has been highly critical of international institutions like the World Bank and the International Monetary Fund (IMF) and their strategies to eradicate poverty. Rooted in Eurocentric conceptualizations of progress and the economic trajectories of the industrial West, these multilateral agencies, it is argued, emerged from a post-World War II, cold war context and have always represented the geopolitical and economic aims of the West. Against the background of decolonization, post-war rebuilding, and concerns about the spread of communism, poverty became a central justification for development interventions and the rise of newly established multilateral institutions focused on integrating recently independent nations into Western circuits of capital (Lawson, 2007; Roy, 2010; Escobar, 1995). As explained by Arturo Escobar (1995), "[i]t was commonly accepted in the early 1950s that if poor countries were not rescued from their poverty, they would succumb to communism" (p. 34). Across the decades of the 1950s and 1960s Keynesian modernization and industrial development policies were prioritized in the global South as a purported means to alleviate poverty, expand global markets, and support democracy. Poverty has thus long been entangled with the policies of influential multilateral institutions like the IMF and the World Bank, providing a key rationalization for the projects of development and the promotion of Western capitalist models of growth.

By the 1980s, neoliberal ideology was profoundly shaping the efforts of global institutions to address poverty. Broadly defined, neoliberal development approaches advocate market liberalization, deregulation, privatization, and fiscal austerity as a means to facilitate economic expansion. The 'Washington Consensus' of the 1990s (see Williamson, 1990) enshrined the rationalities of neoliberalism in development thought, advocating (among other things) the privatization of public services and state enterprises; the deregulation of industries and social welfare programs; the elimination of barriers to international trade; and the reduction of public welfare spending (Lawson, 2007: pp. 84–85; Peck, 2001). These logics were embedded in stabilization programs from the IMF and in structural adjustment programs (SAPs) promoted by the World Bank, a suite of development tactics often referred to as 'shock therapy' for the dramatic restructuring they engendered. Such efforts institutionalized free trade agendas and reduced public expenditures in heavily indebted global South nations and had the effect of dramatically reducing spending on poverty, education, and health care. The poor – comprised disproportionally of women and children – bore the brunt of structural adjustment's 'shocks', including the effects of dramatically reduced poverty supports, deteriorating infrastructure, wage declines, and destabilized domestic markets resulting from trade liberalization (see Benería and Feldman, 1992; Elson, 1991). Rather than alleviating poverty, such programs had the effect of entrenching poverty in the global South. While structural adjustment programs have since been abolished, international development institutions continue to operate from the neoliberal logic that poverty can be solved through market reforms and private enterprise (Roy, 2010; Lawson, 2007; Yapa, 1996).

More recently, development agencies have defined poverty through a social capabilities approach, which emphasizes the social dimensions of poverty including access to education and broader cultural resources facilitating the ability to live with dignity. Jeffery Sachs (2005), for example, sees persistent poverty as an outcome of market failure and believes that development must include infrastructure and health and that rich nations must promote the end of poverty through aid (p. 19). Sachs' ideas about poverty and development are encapsulated in the United Nation's Millennium Development Goals (MDGs).

Geographers and critical development scholars, however, are highly critical of Sachs' ventures. In particular, geographic research has challenged the ways in which his conceptualizations of poverty rest upon a geographic determinism that equates physical geography (rather than political economic processes) with poor places (e.g., Lawson, 2007: p. 13). This is particularly evident in Sachs' contention that 'adverse' geography sustains the 'poverty trap' (Sachs, 2005: p. 59). Scholarship critical of Sachs argues that his solutions to poverty remain entrenched within normative models of economic growth. Sachs' claims about a 'ladder of economic development', for example, are highly reminiscent of Rostow's model of stages of development, which has been much critiqued for its conceptualization of development as a linear trajectory of industrialization based upon the history of the West (Roy, 2010). According to Ananya Roy (2010), Sachs is representative of contemporary attitudes about global poverty that tend to emphasize charity and aid while eschewing questions about the global distribution of wealth, power, and privilege.

Ideas about poverty – and its origins, impacts, and solutions – have played a central role in contemporary development. Indeed, eradicating poverty has been a key focus of international development agendas, even as poverty alleviation strategies have often reinforced the political economic status quo and deepened the need for the most vulnerable.

Poverty, Welfare Reform, and Restructuring in the US

Geographers theorizing poverty in the United States and in the United Kingdom similarly share a concern with political economic transformation and the production of poverty. This research has especially emphasized the restructuring of Keynesian welfare states and the new forms of poverty emerging under the neoliberal transformation of labor markets and public policy (e.g., Kodras, 1997; Wolch and Dear, 1993; Peck, 2001; Wolch and Dihn, 2001; Lawson et al., 2010).

Over the past 30 years, the gap between the wealthy and the poor in the US has dramatically increased, even as neoliberal globalization has facilitated an unprecedented expansion of capital and markets (Piven, 2001). Since the 1970s, workers' median weekly earnings, adjusted for inflation, have *declined* and now remain far below their 1973 peak (Piven, 2001). This wage stagnation has disproportionately affected the poor, as

increasing numbers of full-time, low-wage workers remain unable to secure wages above the poverty level (Schram, 2000). A number of important policy and economic shifts underscore the dynamics of growing poverty and inequality amid increasing wealth. Markedly, following dramatic market downturns and economic crisis in the 1970s, states and firms adopted new strategies to reduce labor costs and to improve the 'flexibility' of global capital (Harvey, 1989). These strategies included a range of corporate policies that destabilized the Fordist contract between labor and capital, such as an increased reliance on part-time, subcontracted, and seasonal labor (Goode and Maskovsky, 2001). Perhaps the most pervasive cost-saving tactic was the relocation of production activities to low-wage locales, first in nonunionized regions of the South, and subsequently, across borders, in nations with low-wage rates and levels of unionization and fewer environmental and labor regulations.

The establishment of regional and multilateral trade agreements lowering trade barriers further enhanced this process and helped to establish a new international division of labor defined by the concentration of manufacturing and production activities in the global South and an expanded – and highly segmented – service sector in Western, industrialized nations. In the U.S., 'flexibility' in employment and production systems led to the rapid growth of a low-skill, poorly paid and benefited workforce, even as there was a parallel expansion of a highly paid financial services sector at the opposite end of the employment spectrum (Piven, 2001). This highly divided labor market was reinforced by state policies that embraced and institutionalized the neoliberal ethos of antiunionization, privatization, deregulation, and trade liberalization (Peck, 2001). These processes unfolded unevenly across space and produced new patterns of wealth and inequality. In industrialized nations, they effectively reduced the power of workers and created dramatic losses for the middle class and the poor.

A concomitant reworking of welfare programs and reductions in federal social welfare programs amplified the unequal impact of economic restructuring. In the United States, an assortment of programs for the poor are popularly referred to as 'welfare'. These programs include cash assistance to families, food vouchers, and Medicaid (health care coverage for the poor). However, the program most closely associated with welfare is the cash assistance program, originally called Aid to Families with Dependent Children (AFDC) and now referred to as Temporary Assistance to Needy Families (TANF). AFDC was created in 1935 following the Great Depression as part the Social Security Act. Though the Act was not without its flaws – most notably its exclusion of people of color, immigrants, and indigenous peoples from supports – it represents the largest and 'most effective antipoverty program' to be implemented in the U.S. (Lawson, 2012: p. 1).

The shifting aims of AFDC/TANF reveal a great deal about changing social and cultural norms in the United States. AFDC was initially designed to address childhood poverty among households without the presence of a male breadwinner (see Boushey, 1997). The federal program provided cash assistance to poor, predominantly white, single mothers who were deemed eligible by case workers and local administrators. Black women, who had long been active in the paid labor market, were largely excluded from the program as a consequence of racialized assumptions about employment outside of the home. Therefore, AFDC was geared toward white single mothers and, in fact, was conceived as a means to keep these women *out* of the labor market (Albelda and Whithorn, 2002).

Overtime, however, there was a significant shift in the emphasis in the program. By the 1970s and 1980s, AFDC became more focused on moving female recipients into the labor force (Mink, 1998). Supported by popular myths about 'welfare queens', increasingly the program gave priority to 'discouraging' behaviors seen to prevent women from paid work, such as childbearing outside of marriage. These efforts were promoted as a means of decreasing welfare abuse and 'dependence'; however, geographic and feminist scholarship has underscored the way in which such language elevated ideals about normative family and gender structures while simultaneously providing the political justification for widespread public welfare disinvestment (Wolch and Dihn, 2001; Mink, 1998; Albelda and Whithorn, 2002). In the 1980s, U.S. President Ronald Reagan – the figure perhaps best representing the conservative rally against liberal social welfare – initiated a 'war on welfare', which symbolized a significant shift away from the 'war on poverty' of the 1960s. Subsequently, federal spending on public assistance programs diminished throughout the 1980s.

Most decisively, in 1996, politicians from both political parities came together to create legislation that ended welfare, slashed funding for welfare programs, and devolved federal responsibility for welfare to the state and local levels. The 1996 Personal Responsibility and Work Opportunities Reconciliation Act (PRWORA) concluded 60 years of welfare as a nationally funded entitlement by eliminating AFDC and replacing it with Temporary Assistance to Needy Families (TANF). This gave states full authority to define who is poor, who is eligible for assistance, and the level of benefits available to those in need. The 1996 Act also mandated a series of new punitive guidelines designed to move recipients from cash assistance to work. Some of these reforms include a significant tightening of eligibility parameters, the imposition of new work requirements, the implementation of strict time limits for cash assistance (a 5-year lifetime limit), and the enactment of criteria designed to penalize particular behaviors, such as out of wedlock birth (Peck, 2001b; Mink, 1998; Wolch and Dihn, 2001). Following the implementation of welfare reform, the number of people receiving cash assistance decreased significantly (Schram, 2006).

Welfare reform is significant to geographic research on poverty for several reasons. First, it signals a clear shift away from Keynesian-style welfare, premised on a federally funded social safety net, to neoliberal workfare, centered on market liberalization, localization, and a retrenchment in social services (Peck, 2001b). This change represents a fundamental re-scaling of poverty policy, such that state and local governments were given increased discretion in the provision of social services, creating sharp spatial differences in definitions of need, eligibility, and entitlements across places. Thus, the rescaling of welfare exacerbates already uneven geographies of poverty.

Second, welfare reform represents a key change in the way that poverty is understood and managed. While poverty and

welfare policies have always been specifically racialized and gendered, social scientists and geographers have increasingly documented the way in which the neoliberal management of poverty criminalizes the poor (Peck, 2003; Bonds, 2009). This body of scholarship connects the retrenchment of social services, the unprecedented escalation of mass incarceration in the US, and the disciplinarity embedded within welfare regimes, to argue that there has been a transition away from the 'social welfare management' of poverty to its treatment through incarceration (Wacquant, 2001: p. 98). Accordingly, incarceration works as a mechanism to manage social divisions and rising insecurity resulting from economic deregulation and public welfare disinvestment.

Together, economic restructuring and welfare reform have reworked geographies of poverty in the United States. The dismantling of the liberal welfare state has created a new economic order that valorizes the market as the solution to poverty. Neoliberal restructuring has thus given rise to new spatialiaties as poverty governance is localized and shifting regulations reframe poverty.

Discursive Constructions of Poverty and Place

Geographic research emphasizes not just the political economic underpinnings of poverty, but also the ways in which it is lived, experienced, and discursively (re)produced. Constructions of poverty and cultural representations of the poor reflect social hierarchies and are infused with prevailing conventions about gender, race, ethnicity, and class. These discourses establish and reinforce distinctions between the deserving poor and the undeserving poor (see Katz, 1989). Discourses about poverty construct and position the poor and shape policies that have very real implications for everyday life.

A significant intervention of geographic research in this area has been its interrogation of the sociospatial underpinnings of discursive representations of poverty. In particular, this scholarship examines the ways in which dominant understandings spatialize poverty, making poverty a simplistic problem of geography rather than one stemming from complex structural and discursive processes. Put another way, place becomes the unproblematized explanatory basis for poverty. For example, Crump's (2002) analysis of discourses surrounding the spatial concentration of urban poverty reveals how the poor are pathologized by culture of poverty explanations that define poverty as reproduced in inner city 'breeding grounds' (p. 583). Such conceptualizations identify poverty as endemic to the inner city – and suggest that poverty can be solved simply by deconcentrating the poor – rather than viewing poverty and the inner city as mutually produced through the sociospatial processes of racism, deindustrialization, disinvestment, and out-migration (Crump, 2002). This uncomplicated understanding of poverty disconnects the urban ghetto – and the socioeconomic processes producing it – from other places (for example, the suburbs), thereby neutralizing the unequal spatial relations that sustain urban inequality. In a similar vein, Lawson (2007) examines the ways in which development narratives conceive of 'failed places' – those in need of outside interventions – and 'successful places' in ways that abstract place from the historical processes and interconnections that have produced poverty in some places and led to the accumulation of wealth in others (pp. 52–53).

Research on the discursive production of the poor and poor places thus challenges the ontological foundations of poverty (Lawson, 2012). Poverty statistics, calculations, and measurements not only enumerate the poor and 'failing places' in need of development (Lawson, 2007: p. 52), they are also generative. That is, these categories have the power to (re) create poverty subjects, poor places, and the stigma of being poor (Lawson, 2012). Consequently, processes of enumeration reinforce material and discursive processes of differentiation that shape actions and the way that individuals perceive their ability to act in the world.

The cultivation of poor subjects and spaces through discourses, measurements, and practices of calculation both reflects and rationalizes prevailing social conventions and ideologies. The material processes producing poverty, especially economic restructuring and the implementation of social policies that have diminished public welfare investments, are strengthened by discursive iterations that describe poverty as the outcome of individual flaws or place-specific deficiencies. Such explanations justify retrenchment, disciplinary practices, and particular development interventions and sustain inequitable economic relations.

Conclusion

In situating poverty and understanding it as both materially and discursively produced in place, critical research on poverty reveals that poverty is not merely a statistic or a '"moral" condition', but rather a 'geographically and historically contingent process' (Goode and Maskovsky, 2001: p. 17). By attending to both the material and discursive production of poverty, critical poverty research analyses how processes of neoliberal economic restructuring and capital accumulation are extended and discursively mapped on to particular bodies and places. Moreover, it is essential to think about poverty relationally; that is, to analyze poverty as created and sustained through sets of relationships between places, between social groups. Such a focus means that research on poverty should focus not just on the poor and on impoverished places, but on all social groups in order to understand how the production of the poverty is intimately connected to the production of the nonpoor (Lawson, 2012; Milbourne, 2004).

While mapping and enumerating poverty remains important for illustrating broad-scale dynamics and the spatial positioning of the poor, critics have warned of the problematic assumptions built in to techniques of measuring poverty, of the dangers of categorizing the poor, and of the limitations of emphasizing patterns over processes. Geographic scholarship on poverty underscores its multilayered dimensions and the interconnected nature of poverty dynamics. This emphasis challenges researchers to think across scales in order to conceptualize poverty as produced through the intertwining of global processes of capital accumulation, macrolevel policy shifts, and social and cultural norms as well as local particularities that give rise to distinct geographies of poverty and opportunity.

Abstract

Poverty can be found throughout human history once a definition of 'relative deprivation' within a given society is accepted. The nature and extent of poverty for much of human history is of course known. In the early modern period in Europe, estimates vary from a small proportion of the population to the vast majority. This article distinguishes between people who belonged to the 'structural poor' (physically or mentally challenged individuals, orphans, widows, and many of the elderly) and the great mass living on marginal lands or insecurely employed (small peasants and handicrafts men, day laborers, serfs, and slaves). It goes on to analyze the causes of poverty and various remedies that have been commonplace since the nineteenth century, and more especially with the growth of ideas about welfare states.

There is no universal concept of poverty, which can be applied to all cultures, societies, or times. Poverty can be defined reasonably only as 'relative deprivation,' within a given society. The size of poverty is unknown for great periods of history. In early modern Europe estimates run from 5 to 10% in wealthier cities to more than half of the population in England 1688 and even more in times of crisis. In all societies physically and mentally handicapped, orphans, widows, and many elderly people belonged to the 'structural poor.' The great mass were, however, those living on marginal lands, or on insecure jobs (small peasants and handicrafts men, day laborers, serfs, and slaves). Varying numbers lived from begging. The causes for poverty can be natural (poor soil, extreme climatic conditions or unreliable weather with periods of dearth and flooding, poor communication because of natural hindrances like mountains or deserts), demographic (large families, sharp population growth), sociopolitical (discrimination of certain groups, classes, or casts), or economic (poor productivity, structural changes, cyclical or occasional crisis). Policies to relieve poverty are known for many centuries. Churches, fraternities and communities, and finally governments tried to help and remove some of the causes for poverty, usually with little success. A decisive step was taken only with the introduction of obligatory social security schemes since the last decades of the nineteenth century.

The Concept of Poverty

There is no universal concept of poverty, which can be applied to all cultures, societies, or times. Nowadays, poverty is usually defined in relation to the medium-income level of a society, and the poverty line is drawn where a family has less than 50% of this medium income available. Such seemingly 'exact' definitions were not possible before general income statistics were generated by statistical offices in the twentieth century (with forerunners in some of the most developed countries in the nineteenth century, and even earlier in some cities).

Some researchers have sought to define an absolute level of poverty by drawing the borderline at the minimum input of calories, which a person needs to survive. But even this definition cannot be used as a universal measure since this minimum differs with age, sex, climate, the individual body, health, and the kind of work a person does. Moreover, poverty certainly begins before a person dies of hunger. Therefore, "poverty can be defined objectively and applied consistently only in terms of the concept of relative deprivation" (Townsend, 1979: p. 31). But what is relative deprivation?

The Size of Poverty

If we were to take present standards of living in advanced societies as a yardstick, most people, probably more than 90%, in all cultures and ages, would have to be defined as paupers. Only rulers, their immediate entourage, and some large landholders and merchants were free of poverty. Most people working in handicrafts or on the land whom we would term today as the middle classes lived at least at the borderline of poverty. When the harvest failed, epidemics arrived, or war devastated a region – and this occurred frequently even in Europe up to the seventeenth and eighteenth centuries – they could be driven into misery. In other regions of the world, where periods of drought or torrential rains recur regularly, it is difficult even today for the majority of people to work themselves out of poverty.

For Western Europe we have sporadic estimates of the size of poverty for single cities and smaller regions since the later Middle Ages, and by Gregory King for a whole country, England, in 1688. They vary considerably, partly because the criteria used often remained vague and depended on the prejudice and purpose of the author or institution taking the numbers. In some relatively well-to-do cities like Toledo, Lyons, Verona, Augsburg, Amsterdam, and Norwich in the sixteenth and seventeenth centuries, the poor numbered between 5 and 10% of the population in 'normal' times, rising to between 20 and 30% in times of wars, epidemics, or harvest failures. Similar figures have been found for some rural hinterlands of such cities, e.g., around Nuremberg or Zurich (Jütte, 1994: p. 53).

According to Gregory King, however, paupers constituted the majority of the population of England at the end of the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62051-2

seventeenth century. While half a million families (comprising about 2.7 million persons) increased the wealth of the country, about 850 000 families (comprising more than 2.8 million persons) decreased it by depending on others for their livelihood (Mathias, 1983: p. 24). Other contemporaries give, however, different figures.

In eighteenth century, French estimates of the size of poverty vary according to the definition between one-third and half of the population. When, during the French Revolution, the definition of poverty was sharpened by excluding beggars, vagabonds, and others 'unwilling to work.' The Comité de Mendicité stated that 39% of the workingmen were not able to support a family of five persons (Hufton, 1974: p. 22).

One can distinguish at least three different measures used by officials in Western Europe in early modern times to count their paupers. The first was to count the recipients of welfare in one way or the other. This depended, of course, on the welfare policy applied at a particular location. Known figures vary from 2% for the city of Berlin in 1665 (but 7.2% in 1799) to 14.8% in Trier in 1623. But it is also known that in nearly all cities, the majority of people who applied for welfare were refuted. (In Amsterdam in 1799, 37 500 received help, while 81 080 were refuted.) The second measure were censuses of the poor. These were rare, and the few available figures vary between 9.5% in Valladolid, Spain, in 1561 and 20–25% in Huddersfield, England, in 1622. The third method is to count the 'fiscal poor': the people (mostly heads of households) exempted from taxes because of poverty. Here we find a much higher level. The lowest available figure is 4.7% for Cologne in 1582 while the highest was 77% for Verona in 1635. Most other cities record shares of the tax-exempt households between 35 and 50% (Jütte, 1994: pp. 46–56).

Taking into account that most of these figures stem from cities in the wealthier parts of Europe, it is easy to imagine the degree of poverty in other regions, particular the notoriously poorer mountainous regions, or the countryside in Eastern Europe, not to speak of the less developed continents.

Who Are the Paupers?

Certain groups of paupers can be found in all cultures and centuries, for instance, the bodily or mentally handicapped who are not able to work, and father- or motherless children (except those who live in extended families). Very often mothers with fatherless children are being reported among the poor. Finally, elderly people, particularly widows, frequently fell into poverty, at least before old age pensions were introduced in the late nineteenth and twentieth centuries. Even then they rarely received pensions high enough to support them. These people can be called 'structural poor.' They probably formed the 5–10% of paupers registered even in well-to-do cities and regions. In addition are those who have become temporarily unable to work because of sickness or injury, particularly during wars or natural disasters. One could term them 'cyclical poor.' Their numbers could swell easily to more than half of the population if events like epidemics, crop failure, or war devastated a region. At such times usually all those who lived on the margin of subsistence – until very recently the majority of the population – fell into deprivation.

All these groups have been seen since the Middle Ages by both worldly and religious authorities as 'deserving poor,' to help whom was a task for church, local or central governments, and private charity. They are to be distinguished from the 'undeserving poor': able-bodied idlers, beggars, vagrants, vagabonds, and prostitutes, who had to be educated or penalized, being expelled or – since the sixteenth century in Europe – put into workhouses or prisons (often one and the same).

For modern observers the biggest group is, however, the 'working poor': small peasants or handicrafts men, day laborers in cities as well as in the countryside, and the unemployed. Nor should slaves be forgotten. Though not all slaves in ancient Europe or seventeenth to nineteenth century America were poor – some had learned crafts or worked as privileged servants, even as artists or managers – the great majority certainly were, and slavery existed also in other cultures and in some European countries as late as the seventeenth and eighteenth centuries.

The Causes of Poverty

For analytical purposes one can distinguish between different causes of poverty but one has to be aware that in reality they often were intertwined. Jütte (1994) distinguishes between accidental, cyclical, and structural causes. Accidental causes are, for instance, sickness, which counted according to the English Poor Law Commission in 1909 for 'at least one-half of the total cost of pauperism' (p. 21). In early modern Europe plague, influenza, typhus, typhoid fever, or smallpox did not only kill large segments of the population, but also impoverished many of those who had survived. Warfare is another 'accidental' cause. Bad harvests, as well as periods of accelerated population growth and structural changes in the economy, Jütte counts as 'cyclical,' while he sees 'structural' reasons mainly in demographic patterns: persistent large families with many children and a nonsecured old age. One would have to add seasonal causes to this typology. In northern countries each winter produced unemployment and poverty.

Another analytic scheme could be to distinguish between natural, demographic, sociopolitical, and economic causes of poverty. In all preindustrial societies man was subject to natural conditions and disasters: drought or flooding, fire, unbearable heat in summer, or ice-cold storms in the winter time could stop his activities, and the natural fertility of his land limited his productivity. Richer or poorer soil, the availability of transport routes on rivers, lakes, and oceans, the availability of raw materials, like wood, copper, or iron ores determined the results of his labor. Demographic factors played an important role – as long as productivity could not be raised markedly, population growth could lead to increased poverty. Sociopolitical factors influenced the degree of, and the distribution of, wealth and poverty in all cultures, societies, and ages. Centralized or decentralized power, the strictness or looseness of social and political hierarchies, the degree and distribution of freedom, serfdom, or slavery among the population influenced also the living standards. Where geographic mobility was restricted, as in the case of slaves and serfs, people could rarely evade poverty by moving to better places. Where upward social mobility was restricted, even hard work could help little to improve the lot of

the lower strata of society. Here India with her caste system is probably the worst case, but Chinese and Eastern European peasants also fared worse than Western European ones, or Europeans in their new settlements overseas. Economic conditions are closely connected to the political and social order. Where market conditions could develop, a growing minority at least had the chance to escape poverty. But economic development did not occur harmoniously and evenly. The rise of one sector or region could cause impoverishment in another. When Dutch and English woolen products flourished in northwestern Europe in the sixteenth and seventeenth centuries, Italian cities suffered from the new competition. When Indian cotton products appeared on the European markets, the European woolen and linen producers had a difficult time, and when the British and Western European textile industries mechanized their production in the late eighteenth and nineteenth centuries Indian calico producers lost out.

Since the Industrial Revolution, numerous such displacements took place and led to regional and branch- or industry-wide pauperization. Most, but not all, were temporary and could be stopped by adjustments to new technologies or other activities. Social and geographical mobility helped to absorb such shocks. There was, however, no overall impoverishment connected with industrialization. On the contrary, rather, the growth of productivity connected with mechanization and rationalization improved even the lot of the poorer segments of the population in the long run. The social problems at the beginning were caused rather by the population growth, which accelerated noticeably from the later eighteenth century. Without industrialization and the growth in productivity in agriculture too, Malthus' law that population grows faster than productivity would not have become obsolete.

There has been a long discussion among economic historians of Britain about whether the standard of living of the working classes during the Industrial Revolution improved or deteriorated. There is agreement that it improved from the 1830s when productivity grew recognizably and regularly and the growth of industry created more better-paid jobs. The pessimistic school maintained, however, that between about 1780 and 1830 the living standard of the workers deteriorated. This discussion suffers from a lack of adequate statistics, particularly of consumer prices and regional differences. As always when structural changes occur, there were winners and losers. The winners were skilled laborers and those who could move to better-paid jobs in growing regions; the losers were the immobile, unskilled people in areas not enjoying growth in industry, trade, and services (Fischer and Bajor, 1967, and an ongoing discussion in the *Economic History Review*).

The discussion was first aired among British social reformers and Members of Parliament in the 1820s and 1830s, culminating in F. Engels' famous book on the situation of the working classes in England (1845) in which he painted an unrealistic picture of the idyllic life of the workers in the putting-out industry and contrasted it with that of the industrial workforce. It was also influenced by the last grave subsistence crisis, which occurred in parts of Western Europe during the second half of the 1840s. Ireland in particular, but also regions on the continent like Silesia, was hit by bad harvests including a nearly total loss of potatoes, the poor man's main food. Millions died or emigrated. The not-yet-mechanized linen industry could not compete with mechanized cotton industry. Pauperism seemed on the rise again, but this was a cyclical rather than a structural phenomenon. Since the middle of the nineteenth century, living standards of workers improved in most countries of Western Europe and North America without, however, erasing poverty. In many countries serious empirical work on the size and causes of poverty began only now, culminating (among others) in the 17 volumes Charles Booth published between 1889 and 1897 about *Life and Labour of the People of London*.

Welfare Policies

There is agreement among students of poverty that (modern) welfare policy began only in the nineteenth century, with the onset of social security schemes. But to care for the poor was seen as a moral obligation in all major religions and it was institutionalized at very early stages of history. Compassion was, however, only one reason for this: the other was fear, for paupers were regarded as dangerous. This twin motivation runs right through the centuries. The second motive, fear, seems to have dominated public policy in the Roman Empire, but early Christians insisted that *caritas* was essential. The Early Fathers of the Church, like St Augustine, preached that poverty was a virtue and some founders of Christian orders, as in the case of St Francis of Assisi, obliged their brethren to adhere to it. The Church and its monasteries were thus the main bodies responding to the fate of the poor during most of the Middle Ages, though not the only ones. Self-help played a role not only among families and neighborhoods, but also in the craftsmen's guilds, which cared for their sick people and sometimes for the widows and elderly masters. Brotherhoods existed not only for journeymen but sometimes also for unskilled laborers, and in the later Middle Ages in some cities such as Frankfort, Strasbourg, or Zurich even for 'the blind and the lame' (Fischer, 1982: p. 29). In other countries, such as Spain, confraternities that enrolled men and, in some cases, women from different occupations, offered mutual aid alongside spiritual welfare to their members. Christian belief convinced wealthier citizens to secure their salvation by giving alms, establishing foundations for the poor, or leaving parts of their fortunes to institutions such as hospitals.

Hospital pauperum already constituted small centers of welfare in the early Middle Ages. Often they cared for 12 persons, symbolizing the 12 apostles. In the twelfth and thirteenth centuries many such hospitals were founded, not only by bishops and monasteries but also by kings, princes, merchants, guilds, and cities. About 600 of such hospitals existed in England in the middle of the fourteenth century. Some of them specialized, for example, in the care of children or of old people, or of those with certain maladies like leprosy. Often they supplied only minimal help, not even food was necessarily provided, and their inhabitants received permission to beg. Medical care was an exception since very few physicians were available. Most of the hospitals in the smaller towns remained all-round institutions for helpless people, but a few housed several hundred people.

In the later Middle Ages cities took over some such hospitals or founded new ones. They installed poor-relief administrators,

who began investigations of individual cases of poverty and made surveys for their towns or districts. Poor relief was to be made more efficient and rational; pure almsgiving was no longer enough. The 'deserving poor' were to be separated from the 'undeserving' ones. Orderly procedures were being introduced in administering poor relief. This was particularly marked in Northern and Central Europe while in France, Spain, and Italy worldly authorities remained more reluctant to take poor relief out of the hands of the Church.

This rationalization and bureaucratization began well before the Reformation, and afterward Catholic and Protestant regimes did not necessarily follow different policies – both, for instance, tried to educate the poor, particularly the children, though with meager results. But there were differences as to the centralization or decentralization of such policies. Mainly Protestant critics centralized their institutions into a 'common chest' to exercise better control. In the German Empire the Imperial Diet of 1497 declared that each community should take measures to care for its own poor, and this principle was enacted in the Imperial Police Ordinance of 1530, which remained in force until the end of the Empire in 1806. Switzerland, the Netherlands, Britain, and the Scandinavian countries followed similar paths, while in the Mediterranean countries the many decentralized institutions remained more or less undisturbed.

While Britain is seen as the pioneer of a general poor tax in 1572, the municipality of Paris had introduced such a tax already in 1551 after the French king had given it the authority "to supervise and conduct all things required for the treatment and the relief of the poor" (Jütte, 1994: p. 119). But Britain pioneered early modern poor regulations in several respects. Already in the middle of the fourteenth century Parliament ordered that the working poor should be distinguished from beggars, and in 1388, tried to restrict the mobility of beggars. From the 1530s to around 1600 numerous statutes were enacted, of which those of 1572 and 1596 became known as the 'Old Poor Laws,' which remained in force until 1834. The judges of the peace had to select four men of substance to act as overseers of the poor. These men had to raise the poor tax, distribute help, and take care of the education of orphans. They were supposed to punish beggars and vagabonds, and could establish houses for correction. As in other countries, the result of their endeavors was very uneven. The poor taxes always fell short of the needs. It has been estimated that only 7% of the expenditure for the poor originated from taxes – by far the greater part came from private donations and charitable trusts, which were established by wealthy citizens. One rich Londoner alone set up institutions for the poor in 216 communities (Fischer, 1982: p. 43f). Such trusts also ran hospitals and schools.

In the minds of the early modern poor administrators and the wider public, education to work became more important than poor relief. Therefore, workhouses were established in the major cities and some smaller towns. The hope was that they would both accustom the poor to work and produce some profit. Usually they failed in both respects. Particularly in the Netherlands, the Scandinavian countries, and in Germany they became rather a combination of workhouse and house of correction, the famous example being the Amsterdam *tuchthuis* founded in 1595. In smaller towns such houses often tried to perform four functions: educating orphans, getting adults to work, penalizing beggars and criminals, and taking care of handicapped or sick people.

The English Poor Law of 1834 was supposed to remedy the ages-old deficiencies in welfare policies. After a Parliamentary Commission had found that the 'Old Poor Law,' by prescribing assistance to every needy person, had actually provided a disincentive to work, the new law stipulated that only such paupers who were willing to live (and work) in poorhouses should get relief. It turned out that there were not enough such institutions to house everybody who did not find work on his own or did not earn enough to survive, particularly with a larger family. The new law did not remove the ancient causes of poverty, neither could it take care of the temporary unemployment of industrial workers, but it revived the discussion about social problems in the country. A whole set of measures had to be taken to improve the lot of the poorer classes: while more employment was to be created by industry, transport business, and services. Parliament regulated child and female labor, and began to enforce safety measures at the workplace, while local communities improved the housing and sanitary conditions. In 1876, about 19% of the population were insured by voluntary Friendly Societies, relatively more than in Germany's obligatory health insurance in 1885, but the most needy could not afford the contributions. Private charity remained, therefore, important in Britain. In 1897, Britain introduced obligatory accident insurance, in 1908 old age pensions, and in 1911 a combined health and unemployment insurance.

Other European countries were faster in creating obligatory accident-, health-, and old-age insurance. But unemployment, one of the most important reasons for poverty, was being regarded as noninsurable even at the end of the nineteenth century. In Germany, unemployment insurance came into force only in 1927. Most of these insurances were quite inadequate at the beginning. They covered industrial workers only in some branches, not day-, farm-, and home-workers, thus excluding the poorest part of the labor force. Bismarck's Old Age Insurance provided means only at the age of 70 when most people had died already, and widows received only 20% of the earning of their husbands in accident insurance. But the principles of a modern welfare state were established, and the basic institutions for it were created before or shortly after World War I.

Abstract

'Poverty law' in the United States refers to policy and lawyering strategies to contest inequality. The rise of the federal welfare state shaped the contours of poverty law in the first half of the twentieth century. This combined with the rights revolution at mid-century to mobilize legal services lawyers and courts in the War on Poverty, which was the zenith of the antipoverty movement. The welfare state's subsequent decline and federal court retrenchment channeled the antipoverty movement in new directions forged by decentralization, privatization, and globalization: moving it *downward* (from federal to local), *outward* (from state to market), and *beyond* (from domestic to global).

Introduction

The United States is a nation of extremes. By gross domestic product, it is the wealthiest country in the world. But it is also marked by persistently high rates of poverty and inequality. The U.S. lags behind peer countries in most indicators of health and social welfare with some of the highest rates of infant mortality, maternal mortality, and teen pregnancy. Life chances are shaped by economic status: poor people are at much greater risk of losing their jobs, housing, healthcare, children, and liberty as a consequence of their poverty. And poverty rates and related disparities continue to correlate closely with racial and gender inequality.

American law and lawyers have long sought to redress the damaging impacts of poverty and inequality. During the last century, government antipoverty programs have gone through periods of expansion and retrenchment, at times achieving meaningful success in reducing poverty. Activist and civic-minded lawyers have fought to establish and enforce rights to basic social and economic goods, often realizing important victories on behalf of poor people. Courts have mediated many of these distributive struggles, sometimes at the vanguard of change and sometimes forestalling or reversing it.

In the U.S., 'poverty law' refers to these interrelated policy and lawyering strategies, which are deployed and contested across a range of lawmaking spaces. The rise of the federal welfare state shaped the contours and content of poverty law in the first half of the twentieth century. This combined with the rights revolution at mid-century to mobilize legal services lawyers and courts in the War on Poverty, which was the zenith of the antipoverty movement. The welfare state's subsequent decline and federal court retrenchment channeled the antipoverty movement in new directions forged by decentralization, privatization, and globalization: moving it *downward* (from federal to local), *outward* (from state to market), and *beyond* (from domestic to global).

The Rise of the Federal Welfare State

The nature of social obligation – what is owed to and expected from fellow community members – is at the core of antipoverty policy. Social welfare programs have often made moral distinctions between the worthy and unworthy poor (Handler and Hasenfeld, 2007; Zatz, 2012). Such distinctions hinge on divergent understandings of the causes of poverty, and reflect prevailing social norms, such as the value of promoting certain types of families. Moral views, in turn, are influenced by economic concerns, which focus on the degree to which aid reduces economic incentives to work and creates dependency, and who bears the cost of any transfer scheme.

These considerations have informed the development of two basic types of aid in the United States: social insurance programs, which are contributory (and what some consider 'earned'); and public assistance or welfare programs, which are non-contributory (and what some consider 'unearned'). U.S. antipoverty policy can be traced along a rough historical arc of increasing federal support for such programs culminating in the War on Poverty. Although political pressure has been placed on both types of programs, the redistributive aspect of welfare has made it more vulnerable, causing the federal role to be both curtailed through burden-shifting to states and localities and rechanneled through market-based mechanisms.

The first national welfare program – and arguably the inception of the modern U.S. welfare state – came in the form of pensions paid out to northern veterans of the Civil War starting in the 1860s. For several decades, Civil War pensions represented roughly one-fourth of the federal budget, and by the turn of the century more than one quarter of all white men age 65 and older were receiving benefits (most southern states adopted their own pension systems for Confederate veterans by the 1890s) (Skocpol, 1995).

During the Progressive Era in the U.S. (1890s–1920s), states established widows pensions directed primarily at poor single mothers in 'suitable homes' (Trattner, 1998). As a result of the Great Depression, many of these state programs collapsed, ushering in a new level of federal investment in aid to the poor. President Franklin Roosevelt's New Deal, enacted during the depths of the Depression, included the Social Security Act of 1935, which: (1) created a state-based Unemployment Insurance program; (2) directed grants to the states for the blind, elderly poor and dependent children (the latter of which we now think of as 'welfare'); and (3) established

contributory insurance benefits for retirees in certain industries (what we now think of as 'Social Security').

World War II led to further expansion of the federal safety net through the Servicemen's Readjustment Act of 1944, popularly known as the G.I. Bill. The G.I. Bill provided extensive assistance to veterans and their families, including extended unemployment compensation, low-interest mortgages, generous business and farm loans, and free educational expenses for college or vocational training. While not expressly targeting the poor, the G.I. Bill kept or lifted many families out of poverty and is often credited with helping to create the post-war middle class (Skocpol, 1995).

But the benefits and the economic gains in the 1940s and 1950s were not shared by all. The Social Security Act of 1935 maintained deference to the states on almost all matters beyond contributory social insurance, leaving behind large numbers of poor people, including non-white mothers, elderly African-Americans, and younger workers of all races who were abled-bodied but could not find work. To appease southern Democrats in Congress, Social Security did not cover mostly black agricultural and domestic workers (Skocpol, 1995). New Deal work relief programs like the Works Progress Administration and the Civilian Conservation Corps employed millions of people, but were short-lived.

The next great burst of antipoverty legislation was a direct outgrowth of internal migration, post-war prosperity, and an emergent 'rights consciousness.' As the South continued to enforce racial segregation and a sharecropper economy, African Americans embarked on a 'Great Migration' to the North and West, drawn to industrial jobs in major urban areas. In two waves beginning roughly in 1910 and 1940, 6 million African Americans left the Jim Crow South to seek a better life. While African Americans made important gains on the employment front, continued discrimination in the private and public sectors helped to fuel both the civil rights and the welfare rights movements.

These movements stimulated – and in turn were supported by – greater public focus on those left behind by the New Deal, powerfully captured by Michael Harrington's 1962 book on the 'other America' (Harrington, 1962). Presidents John Kennedy and Lyndon Johnson responded to this persistent inequality through the New Frontier and Great Society programs. To increase independence and reduce welfare rolls, President Kennedy's 1962 Public Welfare Amendments to the Social Security Act expanded the federal government's contribution to the states for job training, job placement, and other support services to recipients.

In January 1964, President Johnson elevated the federal role further by declaring an 'unconditional war on poverty' and calling upon Congress to enact a multi-prong strategy to confront a 'domestic enemy which threatens the strength of our Nation and the welfare of our people.' As part of the War on Poverty, Congress passed the Food Stamp Act, which converted an agricultural surplus subsidy into a program to assist millions of low-income families. The 1965 amendments to the Social Security Act created Medicare, which provided the closest thing to national health insurance for millions of older Americans; and Medicaid, which provided grants to the states for a subset of the medically-needy poor (mostly those on welfare).

A centerpiece of the War on Poverty was the Economic Opportunity Act of 1964, which created an Office of Economic Opportunity (OEO) to administer a range of innovative and at times controversial social programs. The Community Action Program (CAP) was designed to empower the poor through their 'maximum feasible participation' in local antipoverty efforts. Although successful in building a number of powerful community action agencies in big cities, CAP was criticized for both doing too little and doing too much: some commentators lamented the lack of authentic community input, while big city mayors opposed federal government funding of aggressive local mobilization.

The Economic Opportunity Act included funding for community development corporations engaged in neighborhood-based revitalization efforts through affordable housing and job creation initiatives – thus stimulating the nascent community economic development movement. The Act also established other enduring antipoverty programs, such as college programs for urban youth (Upward Bound), a domestic peace corps (VISTA), and preschool funding for disadvantaged children (Head Start). Praised and decried as expansions of the welfare state, these legislative initiatives were designed to bring low-income urban and rural communities into the economic mainstream through increased opportunity.

Legal Services and the Rights Revolution

The institutional field of poverty lawyering in the United States evolved from the early charity days of legal aid societies, to its federally-funded zenith during the War on Poverty, to a more decentralized and market-dependent system today. The OEO Legal Services Program and the early years of the successor Legal Services Corporation (LSC) marked the high water point of federal support for the legal aid movement and transformed the delivery of legal assistance in low-income communities. Poverty lawyers in this period turned to the federal courts to instantiate and extend core principles of the modern welfare state, first with success, then with increasing failure, marking the end of the rights revolution – and forcing poverty lawyers to pursue alterative advocacy strategies.

Like the welfare state, legal aid traces its roots to the aftermath of the Civil War, when the federally sponsored Freedman's Bureau was created to provide free legal services to newly emancipated slaves in the Reconstruction South. The first legal aid program, New York's Legal Aid Society, was started in 1876 to 'render legal aid and assistance, gratuitously, to those of German birth, who may appear worthy thereof, but who from poverty are unable to procure it.' During the early twentieth century, charitable legal aid organizations spread in poor neighborhoods, where they relied on staff attorneys to provide free services to specific categories of poor clients, and were subsidized, usually very meagerly, by philanthropic contributions. The organized bar was not involved in establishing a legal aid society until 1909 (Cummings, 2004).

Stung by the publication of Reginald Heber Smith's *Justice and the Poor* (1919), which denounced the glaring inequality in legal services, the bar took on a greater role in funding legal aid, stimulating its expansion over the next 40 years. While bar involvement supported growth, it also placed operational

constraints on legal aid work. Controversial clients were generally avoided, cases that could generate fees were rejected, and client income eligibility was maintained at levels acceptable to private attorneys competing for lower-income clients. These limitations, combined with those imposed by charitable and local business funders, led legal aid lawyers to downplay reform-oriented advocacy and concentrate on resolving individual disputes.

Change came in the form of the OEO Legal Services Program, which institutionalized a more reform-oriented approach within a newly created federal agency committed to attacking poverty. The Economic Opportunity Act did not mention legal aid. However, the Ford Foundation funded many programs – including legal services – that informed antipoverty strategies. In *The War on Poverty: A Civilian Perspective* (Cahn and Cahn, 1964), Edgar and Jean Cahn argued that neighborhood legal services should be a part of the antipoverty effort. With others, they persuaded OEO's first director, Sargent Shriver, to fund legal services for the poor.

The location of legal services within the federal government allowed it to depart from the legal aid model. Propelled forward by the power of the federal purse, the new program was freed of constraints that forced bar-funded legal aid societies to adopt an individualized equal access approach. In the program's first 2 years, grants were made to 300 legal services organizations at a level that constituted an eightfold increase over the 1965 investment in legal aid. By 1981, federal funding for legal services reached its peak at $321 million (Johnson, 1974).

Not all legal services offices were activist. Because the government administered legal services funding on a block-grant basis, many legal aid societies that received grants continued to provide individual services and avoid reform activities (Abel, 1985). However, there was an undeniable shift in tone as well as strategy. As the legal services program's first director, Clinton Bamberger, implored bar presidents in 1966:

> We cannot be content with the creation of systems of rendering free legal assistance to all the people who need but cannot afford a lawyer's advice. This program must contribute to the success of the War on Poverty. Our responsibility is to marshal the forces of law and the strength of lawyers to combat the causes … of poverty … [,] remodel the system which generates the cycle of poverty[,] and design new social, legal and political tools and vehicles to move poor people from deprivation, depression and despair to opportunity, hope and ambition. (Johnson, 1974)

Spurred by this commitment – and buoyed by the new talent attracted by the program's prestige and resources – legal services lawyers did in fact employ more aggressive legal tactics: taking a higher percentage of their cases to court than their legal aid counterparts, making over 1000 appeals every year, and bringing 219 cases to the U.S. Supreme Court in the first 5 years of the program's existence (Lawrence, 1990).

Poverty lawyers, inspired by the impact litigation model pioneered by the NAACP Legal Defense and Education Fund in *Brown v. Board of Education* (1954), thus became active participants in shaping poverty law. Courts had, of course, played crucially important roles in the development of poverty law before the civil rights period. In *Helvering v. Davis* (1937) and *Steward Machine Company v. Davis* (1937), for example, the Supreme Court upheld key elements of the Social Security Act of 1935. Yet the emergent rights revolution of the 1960s – powered by the ideal of progressive social change through law centered on the Warren Court – created new energy around poverty law litigation.

Part of this energy was directed at government and business practices affecting the poor. Lawyers at California Rural Legal Assistance (CRLA), for example, successfully sued the state to restore millions of dollars in Medi-Cal benefits, expanded food stamps and school lunch programs, forced the adoption of a state minimum wage for farm workers, and curtailed the importation of Mexican braceros. Legal services lawyers prevailed in *Fuentes v. Shevin* (1972) when the U.S. Supreme Court struck down on due process grounds state statutes that allowed private parties summarily to repossess goods. Poverty lawyers also sought change through regulatory advocacy on welfare, consumer, housing, and other issues within the now-powerful administrative state.

The most high-profile litigation campaign of this era ambitiously aimed to constitutionalize welfare rights (Davis, 1993). Building upon the intellectual foundation of academic work like Charles Reich's *The New Property* (1964) and led by front-line groups and back-up centers, like Ed Sparer's Center on Social Welfare Policy and Law, lawyers won a string of victories that established key constitutional protections for welfare recipients. In *King v. Smith* (1968), a unanimous Court struck down Alabama's 'man in the house' provisions. In *Shapiro v. Thompson* (1969), the Court invalidated welfare residency requirements. And in *Goldberg v. Kelly* (1970), the Court established the right to an evidentiary hearing before reduction or termination of public benefits, which some lawyers hoped would lay the foundation for a constitutionally guaranteed minimum income.

Taken together, these cases substantially limited states' discretion to legislate morality (*King*), restrict eligibility (*Shapiro*), and terminate benefits (*Goldberg*) at precisely the moment when welfare rolls were growing and becoming disproportionately African-American. As a result of this success, poverty lawyers were criticized for expanding the welfare state and contributing to social decline. Like their civil rights counterparts, poverty lawyers were also criticized for assuming too much power, undercutting the movement's organizing base and moving too far ahead of public opinion in ways that invited backlash (Alfieri, 1991).

Down and Out: Poverty Law after the Welfare State

Just as the Economic Opportunity Act marked the legislative apex of antipoverty policy, so too did *Goldberg* constitute the height of the law reform project. Political resistance to and backlash against the legislative and legal victories of the antipoverty movement – and New Left movements more broadly – began to erode support for the robust exercise of federal power to redistribute resources, and created traction for the ideology of small government and limited judicial intervention on behalf of minority rights. These ideas were fueled by, and reinforced, an ascendant conservative movement that reshaped federal policy making and the judiciary.

Beginning with Richard Nixon's 1968 presidential election and the 1969 appointment of Justice Warren Burger, and culminating in the presidency of Ronald Reagan, all three branches of the federal government retreated from the antipoverty project. Federal courts in general and the Supreme Court in particular began withdrawing constitutional support for welfare and other antipoverty policies. The executive branch became less receptive to advocacy by poverty lawyers, who themselves came under attack. And Congress began unraveling the federal safety net.

These shifts did not spell the end of antipoverty law and advocacy, but instead initiated a political realignment that had parallel effects on both law and lawyers, moving policy making, implementation, and advocacy *downward* (to the state and local levels) and *outward* (from the government to the market).

Poverty Law

A crucial lesson of the antipoverty movement was that a progressive law reform agenda asserting the rights of the poor against government bureaucracies and private businesses was vulnerable to judicial and political backlash. Federal court welfare rights retrenchment began with the election of Richard Nixon and his appointment of four Supreme Court justices from 1969 to 1972. Deeming welfare an economic and social issue and not a fundamental right, the Court in *Dandridge v. Williams* (1970) upheld a Maryland law that capped public assistance grants regardless of family size. *Dandridge*, decided only 2 weeks after *Goldberg v. Kelly*, marked the end of the welfare rights movement's litigation campaign to establish a constitutionally protected right to a minimum income (White, 1999).

The Court issued other opinions outside of the welfare rights domain that nonetheless had a significant impact on inequality. Notably, in *San Antonio Independent School District v. Rodriguez* (1973), the Court upheld a Texas school financing regime that resulted in lower per-pupil funding in poorer school districts, holding that education was not a fundamental right and wealth was not a suspect classification for equal protection purposes. This narrow definition of rights and deference to the legislature in the economic and social arena came to define poverty law jurisprudence – and marked the federal courts as an inhospitable venue for poverty lawyers (Brodie et al., 2014).

Nixon also sought to remake the federal welfare state. His 1969 Family Assistance Plan (FAP) failed to garner liberal support – despite its relatively generous assistance by today's standards – primarily because it would have introduced work requirements for most welfare recipients. Although it would not come to full fruition until the 1990s, the effort to tie public assistance to work resulted in the 1975 passage of the Earned Income Tax Credit (EITC), which provided tax credits to working people with children. The administration also succeeded in passing the Community Development Block Grant program in 1974, which decentralized urban antipoverty money by distributing it in block grants to states and localities.

The failure of the FAP and the creation of the EITC actually combined to increase overall welfare spending during the Nixon era, which fed the growing political reaction that found its champion in Ronald Reagan. In the mid-1970s, then-presidential candidate Reagan introduced the 'welfare queen' into the public lexicon. Though his example was both fictitious and misleading – the caricature never represented an actual person, and whites were still the majority of welfare recipients – this barely coded racial critique resonated strongly with a white middle class fearful of losing further economic ground during the 'stagflation' of the 1970s.

Such attacks helped to fuel a grassroots anti-tax movement opposed to 'big government' generally and social welfare spending in particular. Reagan himself rode this anti-tax sentiment to the White House, where he succeeded in reducing welfare state spending. For example, his administration slashed public housing programs by 80%, and promoted market-oriented alternatives, including the Housing Choice Voucher Program (1983), which shifted federal funding from housing production to vouchers given to recipients to use in the private rental market, and the Low-Income Housing Tax Credit Program (1986), which subsidized private companies that invested in affordable housing development.

This populist sentiment was given intellectual heft in the 1980s by critics who challenged existing policies on moral and philosophical grounds. In *Losing Ground* (Murray, 1984), Charles Murray led the moral charge against so-called 'transfers' (not only from rich to poor, but also between low-income people). In *Beyond Entitlement* (Mead, 1986), Lawrence Mead argued that public assistance should come with reciprocal obligations (what he called the 'social obligations of citizenship'). Responses to Murray and Mead that took seriously the role of structural barriers in poor communities, like William Julius Wilson's *The Truly Disadvantaged* (1987), did not hold sway with the voting public and elected officials.

When President Bill Clinton signed into law the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (PRWORA, also known as 'welfare reform'), it was the culmination of several decades of conservative critique of federal control and government spending. Welfare reform ended the 60-year federal entitlement to benefits for eligible families established by the Social Security Act. In its place, PRWORA created Temporary Assistance to Needy Families (TANF) through a block grant program to the states. TANF benefits were lifetime-limited to no more than 60 months and came with stringent work requirements. This federal devolution and emphasis on market-based incentives has become a signature feature of contemporary antipoverty policy.

As the 1990s welfare debate receded, successive administrations have tried to address spiraling healthcare costs coupled with the tens of millions of uninsured Americans. In 2010, President Barak Obama signed into law the Patient Protection and Affordable Care Act (PPACA), which aims to reduce the number of uninsured Americans and slow the growth of system-wide costs. The PPACA is the most important healthcare reform since the establishment of Medicare and Medicaid in 1965, and extends the logic of decentralization and privatization. In contrast to single-payer or government-run systems in most peer countries, the PPACA will rely on market mechanisms implemented primarily at the state level.

The PPACA also reaffirmed the importance of courts in the poverty law movement, with advocates now defending the constitutionality of a law under attack by opponents. In

a bitterly divided decision in *National Federation of Independent Businesses v. Sebelius* (2012), the U.S. Supreme Court affirmed the central provision of the PPACA. The Court held that Congress had the power under its taxing authority to require individuals to obtain health insurance or pay a fine, thus ensuring implementation of one of the most expansive antipoverty programs since the War on Poverty. At the same time, the Court limited the federal government's authority to expand Medicaid, perhaps auguring a new phase in the political contest over the scope and meaning of poverty law.

Healthcare reform reflects another way in which poverty itself – and hence the poverty law movement – has changed over time. By expanding Medicaid to more people and otherwise subsidizing the acquisition of private insurance by those unable to afford it, the PPACA spotlighted the unmet healthcare needs of the 'working poor.' Since the mid-twentieth century, the growth of those living below the poverty line despite holding jobs has been part of a larger story of economic restructuring related to declining unionization, deindustrialization, foreign outsourcing, free trade, and immigration.

Poverty law's traditional concern with safety net programs has thus been extended to policies and advocacy strategies that redress economic insecurity and living conditions produced by unstable and low paying work (Munger, 2002). The expansion of the EITC into one of the nation's largest antipoverty programs underscored both the decline of the traditional welfare state and the expansion of low-wage work. As the scope of welfare benefits shrunk and the number of working poor grew, the movement to advance antipoverty policy – through both policy reform and legal advocacy – has become deeply linked to a broader range of issues relating to economic inequality, including community development, labor and employment law enforcement, immigrant rights, prisoner reentry, consumer lending, and environmental justice.

Poverty Lawyers

Federal support for legal services has undergone a similar transformation. The success of legal services in pressing a redistributive agenda to expand entitlements and reform business practices became a liability as the political winds shifted to the right. The LSC Act of 1974 created the successor to OEO Legal Services, but placed restrictions on program activities and defunded national law reform centers. In exchange for continued government support, legal services lawyers were required to eschew reform in favor of 'access to justice' and individual client service.

The pressure on legal services increased with the presidential election of Ronald Reagan, who was a vocal critic of LSC from his days battling CRLA as the state's governor. As president, Reagan moved aggressively against legal services, proposing to eliminate LSC in his first budget (and every budget thereafter). Congress restored 75% of LSC's funding, but Reagan appointed a hostile board. He also succeeded in shifting a portion of LSC funds away from field offices to support 'private attorney involvement,' which was deemed a less political effort to promote market-based delivery through *pro bono* and Judicare systems (Cummings, 2004).

As with welfare reform, the attacks on legal services reached their peak in 1996, when Congress slashed LSC's budget by another third and imposed crippling restrictions. Congress banned LSC-funded offices from redistricting challenges, lobbying, class action lawsuits, representing most noncitizens, political advocacy, collecting attorney's fees, abortion litigation, prisoner representation, welfare reform activities, and defending public housing tenants evicted for drugs. Most drastically, this legislation prohibited LSC offices from using non-LSC funds to engage in any of the banned activities. Courts have generally upheld the restrictions, though the ban on welfare litigation was struck down, and in 2010 Congress lifted the ban on attorney's fees.

In the face of these challenges, legal services to the poor has not so much declined as changed. Like antipoverty policy more generally, it is now characterized by resource decentralization and greater emphasis on private sector delivery. While LSC funding has decreased dramatically in inflation-adjusted terms since 1981, system-wide funding for legal aid has actually grown because of increases from other sources, particularly state, local, and private funds. Support for legal services was approximately $1.5 billion in 2010 – or almost twice the real dollar value of the high water mark of LSC funding – with at least two-thirds derived from non-federal sources like private giving and state-managed Interest on Lawyers' Trust Accounts (IOLTA), which distributes to legal services programs bank interest accumulated in private attorneys' client trust accounts (Houseman, 2009).

In addition to this shift in funding, legal services has undergone changes in how it is distributed, with a greater role for market-based delivery. A key development is the increasing role of private sector lawyers providing *pro bono* services, which has been driven by several related trends (Cummings, 2004). First, LSC's private attorney involvement mandate – designed to weaken field offices – shifted resources to *pro bono* attorneys. As a result, the number of *pro bono* referral programs has grown from about 90 in 1980 to approximately 900 such programs today, accounting for between one-quarter and one-third of free civil legal services (Sandefur, 2007).

Second, as LSC funding decreased and restrictions were imposed, the bar promoted *pro bono* as a crucial bulwark against the decline of available federal legal aid. In an important early example, the 1983 Model Rules of Professional Conduct for the first time asserted that a 'substantial majority' of *pro bono* hours were to be targeted to 'persons of limited means' or organizations that advocate on their behalf. Other factors have supported the institutionalization of *pro bono*, including the growth in size and number of large law firms, the advent of law firm *pro bono* rankings by *The American Lawyer*, and evolving professional norms of voluntarism (Cummings, 2004; Granfield and Mather, 2009). As a result, *pro bono* service has become a major resource for poor and underserved clients, with large law firm *pro bono* programs leading the way (Boutcher, 2009).

The turn to nongovernmental support and private *pro bono* has involved trade-offs. Market-based funding and delivery mechanisms are not countercyclical. Thus, in a period of economic crisis like the 2008 Great Recession, legal services funding may decrease as a result of lower interest rates on IOLTA funds, shrunken foundation endowments, and reduced individual and corporate giving. Evidence from the Great Recession suggests that *pro bono* activity may also decrease in

times of economic crisis. When government is not able or willing to increase spending to counteract the decline of private supply, the reliance on market mechanisms may mean that legal services to the poor will drop at the very moment that it is needed most.

In addition, coordinating volunteer services across nonprofit and for-profit firms generates significant transaction costs as front-line legal aid providers have to conduct client intake and then spend time finding volunteers willing to take the cases. Despite substantial progress, such as the widespread hiring of *pro bono* coordinators, there are still organizational impediments to *pro bono* activity in large firms. In her survey of *pro bono* activity, Deborah Rhode reported that only "a quarter of surveyed lawyers' workplaces (25%) fully counted pro bono work toward billable hours" (Rhode, 2005).

Finally, the pressure to prioritize billable hours, combined with the lack of strong supervision by partners, may contribute to less than exemplary *pro bono* representation. In *Maples v. Thomas* (2012), the U.S. Supreme Court excused a death row inmate's habeas filing error when his Sullivan & Cromwell *pro bono* attorneys left the firm and failed to inform him – thus causing him to miss the filing deadline. Although such extreme cases are atypical, quality concerns are not. As Rhode reports: "About three fifths of [surveyed public interest] organizations experienced some quality concerns [with pro bono lawyers]; fourteen percent … reported extensive problems, 33% reported moderate problems, and 8% reported limited problems" (Rhode, 2008).

Private sector delivery also raises questions about which clients get which types of services. Within the *pro bono* system, law firms are reluctant to work on cases that threaten corporate client interests; thus, they take fewer cases in the areas of employment and labor law, environmental justice, and consumer law. Overall, the *pro bono* system is more oriented toward individual dispute resolution and less toward systemic reform. This preference reinforces rather than supplements the federal legal services system, where the vast majority of cases pertain to private disputes or individual claims for government benefits.

In the face of continued scarce resources (LSC, 2009), poverty lawyers are pushing in several directions. On one end, advocates are moving away from the goal of full-scale legal representation for the poor and toward limited scope representation (Trubek, 2001). Proponents of 'unbundling' legal services suggest that legal problems can be broken down into smaller parts (writing a demand letter, filing a grievance, attending a mediation session), and that clients and nonlawyers can be trained to undertake some of these tasks through telephone hotlines and pro se assistance centers without the need for lawyers. Critics argue that unbundling, while useful in very basic situations, risks leaving poor people with a second-class version of legal assistance that can harm their interests.

On the other end, the 'Civil Gideon' movement – drawing its name from the 1963 Supreme Court case mandating state provision of counsel for indigent defendants in criminal cases – has pressed for a judicial or legislative right to counsel in civil matters where the stakes are high (Abel, 2009; Pastore, 2009). In 2009, California passed a law providing nearly $10 million to support pilot projects to provide counsel in civil cases involving 'critical issues affecting basic human needs,' such as housing, child custody, and domestic violence. In 2010, the American Bar Association called for the provision of "counsel as a matter of right at public expense to low income persons in… adversarial proceedings where basic human needs are at stake, such as those involving shelter, sustenance, safety, health or child custody…"

The U.S. Supreme Court, however, is not prepared to extend *Gideon* to the civil context, even when liberty is at stake. In *Turner v. Rogers* (2011), a unanimous Court held that an indigent defendant facing jail time for failure to pay child support was not automatically entitled to state-provided counsel. Though five justices held that Turner did not receive due process in the instant case, the Court held that sufficient procedural safeguards could be met with less than full lawyer representation. The Court's refusal to establish a right to counsel in a case threatening a significant deprivation of liberty disappointed Civil Gideon proponents and reinforced the notion that federal courts could not be counted on to advance the interests of poor people. Partly for this reason, poverty lawyers have turned to state courts to litigate Civil Gideon and other important antipoverty issues.

Beyond Borders: Poverty Law in a Global Age

As federal retrenchment has channeled poverty law activity downward to the local, and outward to the market, it has also interacted with increasing globalization in ways that have linked U.S. policy and practice to change beyond American borders (Cummings, 2008). The impact of globalization can be understood from two perspectives. Internally, global economic integration has produced migratory patterns that have placed issues facing noncitizens at the forefront of the U.S. antipoverty agenda. Externally, U.S. poverty law activism has increasingly interacted with the development of poverty law around the world.

Within the United States, globalization has reshaped the composition of the antipoverty constituency and informed the tactical approach of poverty lawyers. The increase of unauthorized immigration in the 1980s and 1990s, powered in part by economic disruptions caused by free trade, confronted poverty lawyers with clients defined by the absence of legal status. As LSC prohibited the provision of legal services to most undocumented immigrants, immigrant rights legal groups emerged to redress the full range of issues caused by legal marginalization and its attendant economic insecurity. Particularly as federal antipoverty policy sought to exclude many immigrants – most notably in the denial of some benefits to legal immigrants in the 1996 welfare reform bill – immigrant rights lawyers focused on reconstituting an immigrant safety net at the state level and advocated for comprehensive immigration reform at the federal level.

As poverty law's client base has become more globalized, so too has its approach. U.S. poverty lawyers facing the limits of domestic advocacy through law have pursued strategic linkages to the international arena. A number of high profile antipoverty campaigns have drawn upon international human rights law and proceeded through international venues. For example, the Poor People's Economic Human Rights Campaign challenged the 1996 welfare reform bill before the Inter-American

Commission on Human Rights as a violation of the Universal Declaration of Human Rights. That it did not aim to win the legal case, but rather to mobilize international pressure on U.S. lawmakers and courts to change domestic policy, both reflected the strategic innovation of the poverty law movement and underscored how far conservative backlash had forced it to travel to advance its claims.

Outside the U.S., countries have made significant investments in poverty law (Cappelletti and Garth, 1978). While the U.S. trails Western European and Commonwealth nations in per capita governmental spending on legal aid (Johnson, 2000), countries in the Global South have incorporated lessons from the U.S. experience – sometimes following the U.S. lead and other times charting a distinctive path. India's legal aid system is based on a constitutional guarantee to equal justice and implemented by legal services authorities (Galanter and Krishnan, 2004). Brazil recognized the right to legal aid in its 1988 constitution and developed a public system designed to provide free assistance in civil and criminal cases (Vieira, 2008). In 2003, China codified a state-sponsored legal aid system that uses government-funded and private lawyers to represent poor people in a range of individual disputes (Liu, 2008). Many other countries have developed state-sponsored and nongovernmental civil legal services sectors.

In addition, U.S. and international funders have directed civil justice resources to support the rule of law and complement international development. Beginning in the 1990s, Northern donors turned to poverty law as a tool to promote governmental legitimacy and increase access to justice. Major foundations like the Open Society Institute and the Ford Foundation – and governmental and international agencies, such as the U.S. Agency for International Development and the United Nations – made significant investments in supporting access to justice (legal aid and *pro bono*) in diverse countries across the globe, including Bangladesh, Bulgaria, Cambodia, China, Hungary, Liberia, Mongolia, Poland, and Russia.

Clinical legal education has also been an important vector of global exchange, with major funders promoting the development of clinics with an antipoverty agenda (Bloch, 2010). The Global Alliance for Justice Education was founded in the late 1990s to facilitate the network of clinical and practice-oriented law school professors from around the world interested in promoting social justice pedagogy. Partly as a result of such exchanges, law schools in the Global South have themselves been important sites for the incubation and practice of poverty law.

U.S. poverty lawyers have played important roles as advisors in developing international programs, which have been greeted with mixed responses by local populations pleased to receive resources but resistant to the imposition by powerful Northern actors of external models untailored to local needs. Thus, as the poverty law movement becomes more globalized, it confronts anew its central dilemma: how to mobilize elite support and leverage public and private resources toward the end of not only transferring resources to poor people, but ultimately building their political power.

Abstract

The issue of low income and poverty has concerned social scientists for centuries. A primary issue is to define poverty precisely, and then to document its extent, consistent with this definition. Several definitions of poverty are presented, along with their advantages and disadvantages. Having identified the poor population, questions regarding the nature, causes, and cures of poverty follow naturally. The process of measuring poverty and analyzing its causes and consequences has advanced social science research in several areas, including identifying the underlying causes of poverty, understanding social mobility, status attainment, and income dynamics, and measuring the behavioral effects of antipoverty policy interventions. It has also contributed to the development of social science methods, including randomized social experimentation, econometric techniques for dealing with selectivity, and microdata simulation modeling.

The issue of low income and poverty has concerned social scientists for centuries. In 1776 Adam Smith linked economic poverty directly with the lack of "not only the commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without" (Smith, 1776: Book V, Chap. II, Pt. II, Article 4th). Interest in this problem was a natural accompaniment of efforts to understand why nations experience economic growth. If the economy of a nation grows, it is only natural to wonder how the fruits of this growth will be distributed among people and why some people are excluded from the benefits of economic prosperity. A primary issue is to define poverty precisely, and then to document its extent consistent with this definition, that is, to count the poor. Having identified the poor population, questions regarding the nature, causes, and cures of poverty follow naturally. The process of measuring poverty and analyzing its causes and consequences has advanced social science research methods and techniques.

The Measurement of Poverty

The most prominent early effort to measure poverty was undertaken by B.S. Rowntree in 1902, in his attempt to assess the extent of poverty in York, England (Rowntree, 1902). Since that time, there have been numerous attempts to measure poverty in a variety of countries or more narrowly defined areas.

Although reducing poverty is a nearly universal goal among both nations and scholars, there is no commonly accepted way of identifying who is poor. Some argue for a multidimensional poverty concept, such as being 'housing poor' or 'health poor' or lacking in social contacts, thought of as social deprivation. Economists tend to prefer a concept of hardship that reflects economic position or economic well-being, somehow measured; that concept has come to dominate the measurement of poverty.

The measurement of economic poverty seeks to identify those families whose economic position, defined in terms of *command over resources*, falls below some minimally acceptable level. In addition to requiring a definition of economic well-being, the measure must specify a *minimum level of well-being* (or 'needs') in terms that are commensurate with 'resources.' Sen (1983) considered the needs standard (or poverty line) to have 'some absolute justification of its own,' a level below which "one cannot participate adequately in communal activities, or be free of public shame from failure to satisfy conventions" (p. 167). An ideal poverty measure would allow for differentiation according to household size and composition and would enable people to compare the level of access with resources over time.

Having determined the measure of household resources, the needs standard – or poverty line – appropriate for various households allows one to compare the level of household resources with its needs, and thereby to indicate if the family is poor or not poor. When this process is followed for all households in a nation (or some other jurisdiction), one obtains the *poverty rate*, or the percentage of the people (or households) in the jurisdiction who are living in poverty.

Within this economic perspective, a number of economic well-being indicators have some claim to identifying the economic position of households. For example, the official US poverty measure relies on the *annual cash income* of a family, and compares this with some minimum income standard or 'poverty line.' Alternative – and equally legitimate – measures suggest that the level of *annual consumption* better reflects a family's level of living, or that some measure of a family's *capability to be self-reliant* or a family's *own assessment of economic well-being* are superior concepts for measuring the level and composition of poverty. No matter which perspective is adopted, a large number of judgments and choices are necessary for developing a concrete poverty measure. For example, if income is taken to be the best indicator of economic status, is annual, multiyear, or lifetime income the appropriate measure? Should we examine pretax, pretransfer income, or income after accounting for taxes and/or transfers? Should in-kind income be counted or not? Each decision implies both a different poverty rate and poverty population and a different set of antipoverty policies. Finally, irrespective of the decisions made,

the resulting poverty measure can be either absolute or relative. The indicator is absolute if the definition of needs is fixed, so that the poverty line does not vary with the standard of living. A relative poverty measure reflects changes in the overall standard of living of the society.

Absolute Income Poverty Measures

The most prominent absolute income poverty measure is that of the USA, which is the only industrialized country to have an official poverty measure. See Ruggles (1990) and Citro and Michael (1995) for further discussion of the US definition and other definitions. Since the late 1960s, the nation has reported on the level of national poverty and the composition of the poor population. This indicator seeks to identify those families that lack sufficient annual cash income to meet what is judged to be their annual needs. The needs indicator is a fixed income threshold, constructed originally as a multiple of the food needs of households of different sizes and compositions. This threshold changes only as the price level changes, but not as average incomes in society change.

This and other income poverty indicators have a particular philosophical basis. The implied social objective is that, together, the community's efforts and those of the individual should ensure that some minimal level of living is attained. Although people may experience hardship in many dimensions – education, housing, food, social contacts, security, environmental amenities – only a sufficiently low level of money income matters in determining who is poor. Such a measure also presumes that money income is a good proxy for welfare (or utility), and that a particular year's income is an acceptable indicator of longer-run income.

Aside from taking exception to the social objective that underlies the official measure, most other criticisms of it focus on the adequacy of the annual cash income measure of 'command over resources.' While the current cash income numerator of the poverty ratio may reflect the extent to which the family has cash income available to meet its immediate needs, it indicates little about the level of consumption spending potentially available to the family. For many families, annual income fluctuates substantially over time owing to unemployment, decisions to change jobs, or changes in health. Even as an indicator of a family's ability to meet its immediate needs, the current income measure is flawed – it reflects neither the recipient value of in-kind transfers (e.g., food or medical care subsidies), which support the economic well-being of low-income families nor the taxes for which the family is liable. Similarly, while current cash income – and hence the official poverty measure – reflects financial flows in the form of interest and dividends from the assets held by individuals, the assets themselves are not counted, nor is the value of leisure (or voluntary nonwork) time reflected in the measure. The arbitrary nature of the denominator of the poverty ratio – the minimum-income-needs indicator – has also been criticized. Given the weak conceptual basis and the crude empirical evidence on which the dollar cut-offs rest, including the equivalence scales designed to account for the income needs of different family sizes and structures, the official U.S. poverty lines are viewed generally as arbitrary.

These weaknesses have stimulated efforts in the US to improve the official poverty measure. In 1995, a panel appointed by the National Research Council issued its report suggesting revisions in the official measure. The poverty thresholds were modified so as to reflect a broader commodity bundle of needs (relative to the food need basis of the current thresholds) and a new set of equivalence scales. Moreover, the measure of resources was revised to include the value of in-kind transfers received by a household and to exclude estimates of the labor and income taxes for which the household is liable (see Citro and Michael, 1995). While alternative versions of this new measure are being published, the new measure has not yet been adopted formally.

Relative Income Poverty Measures

Use of a relative income poverty measure takes into consideration changes in the overall economy (in terms of wages and prices); it stresses the relationship of the resources of a living unit to those available to other living units in the society.

One prominent relative poverty definition, used extensively by the European Community, considers those with incomes less than one-half of the median income to be in poverty, hence reflecting the view that poverty is only meaningful when compared with overall income or spending levels. Often, a one-half of median income standard is used in the analysis of poverty in the European Community, but more recently, a 60% of the median standard has been adopted (see Bradshaw, 2001).

In addition to the arbitrariness of the 50% (or 60%) threshold, this measure has other weaknesses. Critics point out the weakness of a relative measure in assessing the efficacy of antipoverty efforts. Moreover, the relative income standard ensures that the poverty threshold will rise most rapidly in periods of economic growth, during which time those at the bottom of the distribution also experience real growth in both earnings and consumption. Hence, even though poor families may perceive themselves as better-off during a prosperous period, the poverty rate may not fall, thus overstating the poverty problem. As Ruggles (1990) has stated: "poverty cannot decline under a relative poverty measure without some change in the shape of the income distribution as a whole."

Consumption-Based Poverty Measures

A primary criticism of income poverty measures is that the annual income concept on which they rest is a poor indicator of the permanent income (or lifetime resources) of the family unit. Using such a measure, a wealthy family with a well-educated head and substantial assets, but a year of low income, would be classified as 'poor.'

One proposal designed to avoid this problem involves use of measured family consumption to determine poverty status, based on the argument that family consumption is a superior proxy for the family's permanent income, or family command over resources. Slesnick (1993) argues that income measures of poverty are 'severely biased' (p. 2) in that *temporarily* low-income families are regarded as *permanently* needy. The consumption-based poverty indicator proposed by Slesnick uses household real consumption expenditure per equivalent

adult (taken to be the quotient of real household consumption and a household-specific cost-of-living index and an equivalence scale) as the indicator of resources.

Slesnick's consumption poverty measure has been criticized on several grounds. One particularly salient criticism concerns the arbitrary and potentially misleading equivalence scales developed by Jorgenson and Slesnick (1987) that are employed (see Triest, 1998). While other consumption-based indicators (see Cutler and Katz, 1991) have shown a growing poverty rate over the last two decades, the Slesnick measure suggests that poverty in the USA has been decreasing secularly over that period.

In general, the largest impediment to utilizing a consumption-based index is the difficulty of obtaining complete and accurate family expenditure data, at least relative to measuring a family's income. Furthermore, consumption may not fully reflect a family's true well-being; it is possible that simple frugality may be mistaken for poverty.

Subjective Measures of Poverty

An alternative view of poverty is the 'Leyden School' approach, which relies on the subjective responses of individuals to questions that seek their impressions of their own economic position or well-being, relative to some norm (see Hagenaars, 1986; van Praag et al., 1982). As with income and consumption poverty measures, subjective poverty indicators are based on an 'access to resources' concept, but because subjective thresholds change over time, these measures are relative poverty indicators.

Subjective poverty measures are based on survey responses to questions regarding the minimum level of income or consumption that respondents consider to be 'just sufficient' to allow them to live a minimally adequate lifestyle. If families respond that their own level of living exceeds that minimum, it is possible by observing their actual income to infer both a poverty line and a poverty rate. Because subjective measures are based on individual opinions of what constitutes 'minimally adequate' or 'enough to get by,' they require that individual perceptions of these notions reflect the same level of real welfare for all respondents.

A number of subjective measures have been developed and tested, mainly in Europe. Despite rather minor differences in terminology and question phrasing among these measures, they have yielded highly diverse results. The effectiveness of subjective measures is also limited by the nature of the data collection method. Most estimates are based on small sample sizes, yielding large standard errors.

Inability to be Self-reliant as a Poverty Measure

One additional poverty indicator should be mentioned – one that views those who are without the capability to be self-reliant as the ones with the lowest economic position. This view rests on two considerations, one conceptual and the other practical. The *conceptual reason* is the more basic. This position has its foundations in the writings of Sen (1992, 1997), who argued, "that the basic failure that poverty implies is one of having minimally adequate capabilities," (1992: p. 111) and hence that "poverty is better seen in terms of capability failure than in terms of the failure to meet the 'basic needs' of specified commodities" (1992: p. 109).

There is also a *policy-related reason* for developing a capability measure of poverty. In recent years, there has been renewed civic debate regarding appropriate norms and standards for individual responsibility and behavior, and hence the appropriate role of the state. A prominent viewpoint in this debate has emphasized the merits of individual independence (relative to reliance on government programs), the negative effects of government programs on individual behavior, and the desirability of a smaller economic and social policy role for government. If society is to base policy on the central social goal of 'economic independence,' then it would seem important to identify the size, composition, and growth of the population of citizens who do not have the capability to be independent in a market economy.

An example of such a capability-based poverty measure is based on the concept of a family's net earnings capacity (the amount that the adults in a family could earn if they worked full time, full year, adjusted for the constraints on working at capacity due to health problems or disability and the expenses required if all of a family's working-age adults did work at capacity). If earnings capacity is less than a poverty threshold, the family is defined as 'unable to be self-reliant,' and in poverty (see Haveman and Bershadker, 2001). A related measure of family capability is Becker's (1965) concept of 'full income,' which includes both income realized through market work and the value of leisure time.

Measuring 'self-reliant poverty' requires several implicit conventions, norms, and assumptions. For example, such a measure is reliable only if the 'norm' of full-time, full-year work is an accepted, socially determined norm representing the full use of human capital. Of necessity, attribution of poverty status to any particular family requires prediction from statistical estimates rather than values measured in survey data (such as income), and hence may be viewed as less objective than, say, income-based measures.

The Analysis of Poverty

Since the mid-1960s and the US declaration of a War on Poverty, social science researchers have addressed a number of issues concerning the nature, causes, and cures of poverty. In the process, substantive additions to economic knowledge and to research methods have been developed.

Understanding the Determinants of Poverty: Demographics, Discrimination, Human Capital, Immigration, and Macroeconomic Performance

A major objective among social science researchers has been to understand the processes which combine to result in some people failing to attain minimal standards of economic well-being. Although the number of such processes and institutions is very large, and the interactions among them are complex, research has been concentrated in several areas.

The underlying *demographic structure* of the population – age, gender, family arrangements, fertility choices – plays a major role in determining whether families or individuals

are poor. For example, the share of the population that is elderly, and hence unable to be self-reliant through work and earnings, influences the prevalence of poverty in a society. Research has tracked the poverty status of the older population and evaluated the ability of older people to escape poverty given their own resources and social support. Similarly, changes in the prevalence of single-parent families caused by rising divorce and non-marital childbearing rates are also fundamental determinants of poverty. Families with children but only a single adult tend to be restricted in their ability to be self-reliant from own earnings. Social scientists have studied the trends and determinants of these choices in an effort to better understand the causes of poverty.

If the attitudes of the majority of the population toward minority groups are such as to lead to lower payments for equivalent work or to inferior schooling, housing, or mobility opportunities, poverty rates among minority groups would tend to be high. Given the prevalence of racial minorities among the poor population, the possible causal role of *labor market, education, and housing discrimination* has been an important topic of study, especially by economists. While the existence and extent of racial income gaps had been studied prior to the 1960s, later research delved deeper than previous work in measuring and explaining the sources of these income gaps. See Cain (1986) for a review of this line of analysis. Given that competition would be likely to erode the effects of discriminatory behavior by employers (Becker, 1957), research turned to explanations involving 'statistical discrimination' and 'market signaling' as the basis for continued discrimination as a cause of poverty.

The role of *education and training* – human capital – in enabling people to attain self-sufficiency also became a focus of poverty research and analysis. The question of the effect of increases in schooling on individual earnings occupied the efforts of numerous researchers, and education came to be analyzed as a process that created human capital. Estimates of the rates of return on schooling seemed to justify diverting resources from private sector investments in physical capital to public investments in education. Rosen (1987) surveys the literature in this area. While economists focused on the earnings returns from schooling, other social scientists sought to document the effect of schooling on student attainment (such as test scores), social mobility, and economic status. This research documented the complexity of the processes by which some children succeed while others fail, and led to a search for improved data and statistical methods capable of disentangling the effects of education on attainments. This 'human capital' approach to schooling carried over to numerous studies of the effectiveness of governmental programs designed to provide skills and training to adult workers. See Heckman and Lochner (2000) for a review and interpretation of the evidence on the economic effects of education and training.

Concern with the problem of poverty in the USA coincided with a rapid increase in *immigration*, often of individuals with low levels of schooling or language competence. The potential impact of immigration in eroding wage rates for unskilled workers in urban labor markets containing large numbers of immigrants became an important policy and research issue.

The effect of the overall performance of the economy on the poverty rate was also the subject of substantial research and analysis, beginning in the 1960s. During the 1970s, economic growth and low unemployment seemed to be powerful instruments in reducing unemployment. However, during the 1980s and early 1990s, economic growth seemed to have lost its antipoverty effectiveness. Evidence suggests that during the 1990s, the level of poverty was again responding to macroeconomic performance. See Haveman and Schwabish (2000) for a review of this research and for recent evidence.

Understanding Social Mobility, Status Attainment, and Income Dynamics

Research on the causes of poverty have tended to focus on static issues – factors that appear to be causally related to low economic position. Simultaneously, a complementary line of research addressed questions of the dynamic processes by which people either succeed or fail to attain economic position – processes that indicate the openness or fairness of society. While research on these social mobility processes had been undertaken prior to the 1960s, those studies were limited by the absence of both a conceptual framework and data on individuals over time – longitudinal data – necessary to trace these dynamic patterns. The early 1960s witnessed a number of important research contributions designed to increase understanding of the process of social mobility. One of the most central of these presented a causal model of the socioeconomic life cycle, distinguishing the interactions among three primary life phases: family, schooling, and work (see Duncan and Hodge, 1963). The socioeconomic status of the job was taken to be the ultimate indicator of success, with family back-ground and schooling (as an intervening variable) viewed as the determinants of that status. This framework stimulated several empirical studies of these relationships, yielding insights into changing intergenerational correlations involving occupations and income, changes in the degree of social mobility, changes in the role of education in fostering mobility, and changes in mobility patterns between whites and nonwhites. A variant of this approach sought to identify the factors that contribute to social or economic status, distinguishing those that relate to exogenous family and background factors from those amenable to policy influence. Two prominent examples of this approach are Jencks et al. (1972, 1979). Family characteristics and choices and intellectual inheritance were seen as playing important roles, but school quality and the racial mix of neighbors and peers were found to be less important. Haveman (1987) reviews and critiques this research.

While these analyses were revealing, they demonstrated the difficulty of making progress in this area without detailed data on individuals and families that tracked their attributes and performance over time. The Panel Study of Income Dynamics, the National Longitudinal Surveys, and the Survey of Income and Program Participation are among the most prominent and high quality of these data collection efforts. Extensive use of them has enabled major advances in understanding the nature and causes of poverty, including the lengths (or persistence) of poverty and welfare stays among the poor, trends in income

trajectories among families with various characteristics, the identification of the long-term or permanently poor population, and estimates of the relative roles of family background, schooling choices, neighborhood characteristics, and labor market discrimination in determining the probability of being poor. A complementary field of study has used these data to explore the determinants of these family characteristics (e.g., poverty-level incomes, single-parent status, low parental education, welfare recipiency), schooling quality, neighborhood characteristics, and own schooling and fertility choices on a variety of children's attainments (see Haveman and Wolfe, 1995; Duncan and Brooks-Gunn, 1997).

Antipoverty Effects of Policy Interventions

Poverty researchers have also sought to describe the various policy measures in place to assist poor families and to identify changes in or alternatives to these policies that might be effective in reducing poverty. Probably because the main anti-poverty efforts were in the area of income support measures, analysts concentrated their assessments on such policies. A voluminous literature describing the nature of income support policies and critiquing their incentive (efficiency) and equity characteristics has influenced policy changes over the period since the 1960s. These analyses revealed low 'take-up' rates among people eligible for support, horizontally uneven support patterns among equally poor people, the uncertain rationale for and implications of providing support via in-kind benefits versus tax subsidies versus cash transfers, the relative effectiveness of alternative programs in reducing poverty rates or the intensity of poverty, and the presence of incentives for undesirable behaviors (e.g., reductions in work, increases in family breakups, and nonmarital childbearing) implicit in the structure or administration of the programs.

These descriptive and policy analysis studies played an important role in guiding numerous antipoverty policy reform efforts that have occurred over the past several decades, including proposals for 'negative income tax' plans, work-related subsidies, the substitution of in-kind for cash benefits, and 'welfare-to-work' initiatives. They also provided a catalog of important questions for which answers would be relevant in designing effective policy: how large are work effort reductions in response to income transfers? Has public income support reduced family stability, increased unemployment, reduced savings, or increased nonmarital childbearing? (see Haveman, 1987).

Labor Supply, Family, and Fertility Effects of Income Support Policy

Concerns with the work incentive effects of income support policy have dominated debates over this antipoverty strategy. Numerous analysts responded to this concern with empirical studies documenting the extent of these behavioral responses to public income support programs. These studies, employing a variety of survey data and empirical methods, found that public benefits tend to reduce employment probabilities, lower work hours per year if working, and possibly reduce wage rates among both recipients and potential recipients of benefits.

Most of the early studies employed cross-sectional survey data in order to measure the responses of individuals to the increased income from transfer benefits and the reduced effective wage rate associated with working. Later studies relied on the results from carefully designed 'social experimental' studies of these potential responses (see below). The essential characteristic of these studies is the random assignment of families to alternative forms of transfer program designs (in terms of the generosity of income guarantees and the extent of 'benefit reduction' rates), and the observation of the behavior and performance of these families over subsequent years. Both forms of studies confirmed that, as expected, work effort falls as nonlabor income rises and as the effective wage rate falls. While the estimates varied widely, nearly all of them raised serious questions about the efficiency and effectiveness of this income support approach to helping poor people.

While these studies focused on the work effort responses of people to the availability of income support, other analyses (including randomized approaches) tested the family structure, childbearing, health care utilization, housing quality, and welfare utilization choices of low-income families in response to both welfare-type policies and reform efforts in the educational, housing, health insurance, and public employment areas. Danziger et al. (1981) and Moffitt (1992) have surveyed this research.

Poverty Research and Social Science Methods

In addition to adding to the body of knowledge regarding the nature, causes, and cures of poverty, the growth of poverty-related research since the 1960s has also contributed to the development of new research methods of general applicability in the social sciences (Haveman, 1987). Four contributions deserve mention.

The first contribution consists of a new field of evaluation analysis and research. As analysts, in response to the demands of policy makers, focused on the poverty problem, an emerging analytical area, evaluation research, was also being spawned. Interest in this applied research approach extended far beyond the poverty issue, but research on social and antipoverty policy issues provided this then-nascent subdiscipline with some of its basic methods and case studies. Without the emphasis of policy makers on the need to evaluate the effectiveness of the numerous new antipoverty initiatives, it is unlikely that this field of analysis, with its journals and professional organizations, would have developed as rapidly as it has, and in the same directions.

Second, as noted above, randomized social experimental research was first applied to proposed policy interventions in the poverty area – the negative income tax proposals, school and housing vouchers, employment and training measures, and so on. Without the emphasis on the effect of antipoverty policy interventions on family economic status during the 1960s and 1970s, it is unlikely that this important social science research method would have attained the status it now holds among social science researchers.

One of the problems that analysts face in assessing the effects of policy and other changes on the behavior of people is

the need to rely on samples of observations that may be composed of individuals who are selectively included in the sample, and hence unrepresentative of the larger population for which inferences are desired. This concern dominated the study of labor markets well before demands to assess the impacts of antipoverty measures, especially in the employment and training area, where factors that determined the presence of a person in a research sample were also determinants of the effect that was being studied (see Ashenfelter, 1978). Several approaches to this problem were developed by econometricians (see especially Heckman, 1979), and these statistical tools became a standard part of applied statistical analyses.

Finally, in part because of the development of large representative samples of national populations, analysts began developing computer models designed to simulate the effects on the income, well-being, and behavior of each observation in a data set of actual or proposed policy measures. The application of such microdata simulation models found its most welcomed audience among analysts concerned with the effects of changes in taxation and income transfer policy on low-income families. Without the impetus provided by the need to assess the impacts on poor people of proposed policies, this advance to predictive model building would not have occurred. This research methodology is assessed in Citro and Hanushek (1991).

Abstract

Antipoverty policies include social assistance programs and 'safety nets' for low-income individuals and households. These policies place a floor under consumption levels or provide a minimum income by transferring cash or in-kind assistance or redistributing access to assets or services. Although some transfers are universal, antipoverty policies typically target social categories or apply means tests for benefits, thereby defining who is poor and deserving of aid. Recent reforms made entitlements to assistance more conditional on work requirements or other active obligations.

Definition and Overview

Antipoverty policies include social assistance programs and 'safety nets' for poor and vulnerable individuals and households. These policies place a floor under consumption levels or provide a minimum income by transferring cash or in-kind assistance or redistributing access to assets or services. Some antipoverty benefits are universal rights of citizenship, while others are conditional on fulfilling obligations. Typically, social assistance policies target categories of people who face risks associated with the inability to work – the disabled, the elderly, expectant and new parents, the unemployed. Such benefit programs may apply means tests of eligibility, developing official poverty thresholds that define who is poor and deserving of aid. Poverty measures are also used to monitor and evaluate the performance of antipoverty policies over time. Antipoverty policies are typically financed from general taxation rather than personal contributions to insurance against risks over the life course. However, unemployment, disability, and old-age benefits also prevent destitution among former workers.

Historically, religious charity to the needy preceded public antipoverty programs. Private nonprofit aid programs, sometimes encouraged by public subsidies or tax exemptions, supplement public assistance to varying extents. Public programs may provide resources through tax systems as well as monetary and in-kind transfer payments. The structure or mix of taxes may entail trade-offs with poverty reduction. Contrary to conventional wisdom in economics, progressive income taxes can reduce poverty without necessarily reducing economic growth. More expected, payroll taxation does apparently reduce job growth. Tax credits to top up low earnings may discourage added work hours.

Recently welfare states have reformed guaranteed entitlements, making benefits more conditional. Like the historical workhouses, programs increasingly enforce work requirements or other active obligations of the poor in return for assistance or 'workfare.' However, working is no guarantee of escaping poverty. In recent years, the number of working poor has increased. Rising employment rates have not reduced aggregate poverty in many countries of the world. Therefore, antipoverty transfer policies are supplemented by tax credit and other programs like mandatory minimum wages that 'make work pay.' Training services indirectly enable poor people to leave poverty on their own. These are sometimes called preventive, promotion, or enabling policies, activation, or social investment.

The notion of social investment currently widespread in the European Union (EU) points to the ways antipoverty policies contribute to the overall public good. Indeed, some antipoverty policies contribute to economic growth by enhancing worker productivity. Even when the business cycle turns down, benefits maintain aggregate demand or reduce unemployment. Antipoverty programs may also contribute to social peace and public order. These societal benefits help justify general taxation to pay for social assistance.

Antipoverty approaches and institutions vary widely across regions of the world. The Anglo-American approach emerged from early, local-level poor relief policies establishing the principle of 'less eligibility' and distinguishing between the deserving and undeserving, able-bodied poor. Increasingly this 'neoliberal' distinction is discerned in conditional cash allowances adopted in developing countries. In contrast, socialist and social democratic antipoverty policies traditionally minimized the distinction between workers and the dependent poor, emphasizing full employment and universal citizenship rights to a minimum income. The European Council's Recommendation 92 of 1992 recognizes "the basic right of a person to sufficient resources and social assistance to live in a manner compatible with human dignity." Yet, even in European countries with a right to a minimum income, there is a trend toward encouraging more active participation of social assistance recipients.

History and Development of Anti-Poverty Programs

Public policies to help the poor evolved from religious charity. For millennia, poverty was considered inevitable, but could be alleviated by benevolence. Even today, charities and religious institutions at all scales of operation provide assistance and services to poor people in much of the world. In Europe, government involvement in managing poverty began at the local level in response to pauperism and itinerant laborers.

The earliest publicly financed 'workhouses' were found in Amsterdam around 1600, but, in line with mercantilist thinking, developed extensively in Britain. The Elizabethan Poor Laws instructed parishes to provide 'poor relief' for old age, widowhood, disability, illness, or unemployment. Initially restricted to residents, the 'workhouse' or 'indoor relief' included all those dependent on aid, from the disabled to unwed mothers, who were obliged to contribute to their own support and refrain from immoral conduct.

Prior to the late eighteenth century, the dominant school of economic thought saw poverty as a social good, essential for economic development because it enforced the work ethic, kept wages low, and created a globally competitive economy (Ravallion, 2013). Such liberal welfare principles attribute poverty to individual causes or personal characteristics, such as insufficient investment in human capital, or to bad choices and moral failings, such as promiscuity or insufficient work effort. In 1834, Britain amended its Poor Law because parishes had provided a minimum level of subsistence that exceeded the level of wages. To remove this apparent work disincentive hindering the rise of a labor market in this first industrial nation, the Poor Law reform established the general principle of 'less eligibility' in which relief or public assistance in workhouses had to be less generous than what workers could earn in wages. Anglo-American welfare programs have retained this principle by keeping wage replacement levels in social assistance programs low, eligibility rules narrow, and work requirements strict. For example, at the turn of the twentieth century, Seebohm Rowntree inquired into the wages of the poor relative to the minimal subsistence costs for housing, clothing, fuel, and food, identifying a basic diet of 3478 calories per day. Low benefit levels and narrow eligibility for welfare thus 'regulate the poor' and discipline the wage labor force.

Except for relief under the Poor Laws in England and Wales, there was little increase in the low levels of private or public support for the poor for most of the nineteenth century. Gradually, the poor were sorted into categories. Those considered 'deserving' of public support were provided 'outdoor relief' and could live independently, while others deemed able-bodied were considered 'undeserving' of help and put to work in return for support. These categories persisted so that today, the sick and disabled, women and children are still disproportionately poor and dependent upon distinct programs of social assistance.

Beginning in the late nineteenth century, after numerous cycles of boom and bust, industrializing societies began to establish social insurance programs to cover temporary poverty among able-bodied workers who suffered from job losses or accidents that were no fault of their own. By contributing to insurance funds during good times, workers could protect themselves from the risk of destitution during recessions or incapacity. Thus, for much of the twentieth century, poverty programs *sensu stricto* shrunk to cover small categories of people – widows, the aged, and the infirm – who were not expected to work in the labor market. Often, local governments were charged with providing social assistance for these special needs populations, in contrast to nationalized social insurance funds that created large risk pools.

After the Oil Shocks of the 1970s, welfare states began to change. Slower growth, higher unemployment, and population aging raised fiscal concerns that existing social protection commitments were unsustainable. These 'austerity' conditions prodded many countries to institute 'neoliberal' reforms, cutting social expenditures relative to GDP, tightening eligibility, lowering benefit levels, shortening terms for assistance, and enforcing conditions in return for public support. This is not to say that different welfare regimes began converging, but they were changing in similar ways.

Distinctions among Poverty Programs

Antipoverty programs differ in many respects: eligibility rules; scale and method of governance; activation or work conditions; benefit levels; adjustment for household, life stage, and other categorical differences; administrative costs; and total budget. During the postwar era, mature Western welfare states usually distinguished between insurance against risks and assistance with current needs. This distinction is crosscut by one of universalism versus categorical programs. Universalism entitles all citizens to benefits by right, in contrast to categorical programs that restrict assistance to particular groups or conditions. Universalist programs have been effective at poverty reduction although their effects on inequality vary. Even if low-income households do not receive higher benefits than affluent ones, the benefits constitute a larger share of the poor's total income. Universal pensions may provide a minimum income to all elderly citizens regardless of prior earnings, but better paid workers often enjoy greater or supplemental old-age payments. In turn, taxes may claw back the higher income. Unlike universalist 'social democratic' welfare states, 'Bismarckian' systems, widespread in Continental Europe, are less progressive in the sense of reducing inequality. Even if they offer a floor of income, they tend to preserve inequalities derived from current or prior earnings. In contrast, 'social security' in the US pays retired low-wage workers more than they contributed over a lifetime, while capping maximum payouts to high earners. This progressive system is credited with reducing poverty among older Americans even though the payroll taxes financing it are also capped and regressive. Recent cross-national research suggests poverty rates decline with a larger share of transfers in household income, with homogeneity of transfers, and with targeting of transfers on low-income households.

Categorical programs tend to be more efficient than universalist ones at targeting those in greatest need. The categories vary, but usually include those whom society does not deem able to work. They may include people with disabilities, the aged or children, and sometimes, home-based caregivers, expectant mothers, or lone parents. Aid to single nonworking parents has been declining, while paid parental leave from work has increased. The efficiency of targeting those in greatest need may reduce the overall cost of poverty programs, but savings may be offset by increased administrative costs to police eligibility. Targeting also undermines broad political support.

Categorical programs may or may not 'means-tested.' Sometimes categorical programs like family allowances are universally provided to parents with equal benefits per additional child, regardless of means, but when poor households have

higher birth rates, they may disproportionately benefit. Universal child benefits may also be taxed based on income, clawing back public resources from wealthier families. Nevertheless, eligibility for antipoverty programs per se is usually restricted to those who can demonstrate a lack of other resources, including insurance coverage. Providing means-tested subsidies through the tax system eliminates the expensive and stigmatizing process of documenting assets and income and of meeting a case worker that traditional social assistance or 'welfare' programs often require.

Finally, transfer payments may be made in money or in-kind. Food, housing, and other voucher programs not only have higher administrative costs than cash assistance, but the visible redemption of vouchers also subjects recipients to stigma and shame. In-kind assistance also conveys a society's distrust of the poor, questioning their ability to make good choices. In contrast, minimum or basic income programs often rest upon a guaranteed human right to subsistence.

Entitlements versus Conditions

Social assistance may be provided as of right or on condition that the poor meet obligations. Most mature welfare states now have minimum income schemes that support those below a recognized threshold and who have no recourse to contributory insurance protection. Rather than being targeted at social categories, minimum incomes are quasi-universal, offering a guaranteed right to support. They vary widely in generosity. Countries with the most generous and effective minimum incomes see them as social safety nets that prevent the unemployed from becoming so demoralized and excluded that they are incapable of social participation or effectively seeking work.

A basic income guarantee (BIG) is an unconditional, universal, government-insured citizen entitlement to enough income to meet basic needs. In theory it is not means-tested, so it costs less administratively than even a negative income tax, although it may have potential work disincentives. The guarantee makes it possible for poor individuals to make high-return investments in job search, child care, etc. that poverty might otherwise make prohibitive. An example of a BIG is the South African Child Support Grant, an unconditional, means-tested cash transfer program introduced in 1998. One study found that receiving a Child Support Grant was associated with increased school attendance, decreased child hunger, and increased broad labor force participation, while it had no identifiable effect on narrow labor force participation or employment.

Related to BIGs are work guarantees, albeit in unskilled jobs at low minimum wages. In India, the Maharashtra Employment Guarantee Scheme, started in 1973, became the model for the national Mahatma Gandhi National Rural Employment Program, passed in 2005. The latter guarantees landless laborers and small farmers the right to a minimum of 100 days of paid work per household per year. Because of administrative limitations, however, it is forced to ration the work, providing 50 days of employment a year to around 50 million households. Almost half of the beneficiaries are women, reducing their high poverty gap. In 2001, India's Supreme Court also mandated the provision of cooked lunches to all primary school children. The mid-day meal program distributes surplus grain to about 55% of Indian children. According to the Center for Social Equity in New Delhi, the program has a demonstrable effect on school attendance, especially of girls, and encourages caste mixing.

In contrast to such guarantees, social assistance may be made contingent upon work effort or other conditions, such as motherhood or disability. Traditionally, minimum income and categorical means-tested programs expected able-bodied beneficiaries to seek work, but these obligations were not strictly enforced until recently. Beginning in the 1980s in the United States, mature welfare states have reformed their 'passive' social assistance benefits requiring little in return into programs 'activating' recipients to engage in work or other forms of social participation.

'Workfare' is a derogatory term for mandatory work or community service requirements in return for income support. Many consider these requirements to be a punitive throwback to the nineteenth-century 'workhouse' or a form of 'labor recommodification.' The term originated in the United States where, after many state-level experiments, the 1996 welfare reform (Personal Responsibility and Work Opportunity Reconciliation Act) imposed work requirements on single parents receiving Temporary Assistance to Needy Families (TANF, which replaced Aid to Families with Dependent Children, also known as 'welfare.'). 'Workfare' included carrots and sticks. Although progressive states added funding for work supports, such as child care subsidies, subsidized health insurance, nutrition assistance, transportation and clothing allowances, conservative states introduced more punitive measures, such as family caps, sanctions, and lifetime time limits on support shorter than the federal one of 5 years. Many applicants lost benefits if they did not accept community service requirements, even because they were attending school. Others were diverted to 'work first' before they were ever granted benefits.

Welfare reform had the effect of halving the number of beneficiaries on the rolls. Mandatory work (or work-related activities) reduced welfare use and increased earnings and employment. More generous child care subsidies also promoted maternal employment. But welfare reform also increased the number of 'working poor' households, i.e., those with insufficient earnings to move them above the poverty line, who more than ever relied on other support services and tax credits to survive. The expansion of the Earned Income Tax Credit as people were moving from welfare to work did help 'make work pay.' Negative income taxes like Earned Income Tax Credits are poverty policies based on neoliberal assumptions that welfare undermines work incentives and creates poverty traps, and employers need wage subsidies to price welfare recipients into work.

Most of the evidence suggesting positive impacts of welfare reform was collected during a period of economic expansion, prior to the Great Recession. Initially, the most economically disadvantaged families received the largest amount of support, but by the mid-2000s, families that near or just above the poverty line received substantially larger transfers than in the past. It is too soon to assess how well the program served as a safety net during the Great Recession. Welfare rolls did rise

from 2007 to 2009, but TANF still had work requirements and time limits.

Minimum Incomes and Activation

While liberal welfare states offered low welfare payments and short-term unemployment benefits, Continental Europe long considered social assistance policies to be marginal to the welfare state. Assistance addressed 'residual' or categorical needs not covered by social insurance, was financed from general taxation, and was provided locally with poor transparency. Some needy people were uncovered and fell through the cracks in the safety net. In fact, France had no universal minimum income program until 1988, and Portugal introduced one as late as 1997. Since the 1980s, as high unemployment persisted, more and more jobless Europeans remained on relatively generous unemployment insurance benefits. Gradually, benefit durations were shortened, replacement rates reduced with time, and more employment services provided. With rising costs, welfare states tried to shift long-term unemployed insurance recipients into less generous social assistance or merged the programs, as in Germany's Hartz reforms. Over time, minimum income or social assistance recipients increased, suggesting a spiral into 'social exclusion.'

Therefore, most European minimum income programs have adopted stricter tests on ability to work, enforced job search obligations, required jobseekers to accept employment offers even in different occupations and at lower wages than before, and instituted 'activation' policies. Activation programs differ from 'workfare' in that they activate not only social assistance recipients but also those receiving unemployment, disability, and other benefits, they may use taxes and benefits as incentives, and they may require activities besides paid market employment (Lodemel and Moreira, 2014). These activities may include participation in public or subsidized employment, or in other activities, such as training and job search. Activation schemes often target hard-to-employ groups: the long-term unemployed, ethnic minorities, lone mothers, and so on.

Activation programs are modeled on the active labor market policies (ALMP) of the Nordic welfare states. These policies discouraged long-term dependence on what were, comparatively speaking, generous minimum incomes. Besides the macroeconomic intention of income maintenance during downturns, the whole complex of Scandinavian welfare state institutions – health, education, training, employment services, labor exchanges, transportation, child care – worked together to keep people employed through relocation or retraining or to rapidly moving them back into jobs in demand before their skills atrophy. Yet Nordic ALMP rests upon a whole range of human services, usually public, that do not exist elsewhere. Also, unlike activation of minimum incomes, ALMP eligibility was not tied to income.

Nordic welfare states reconcile decommodification policies insuring basic needs with policies encouraging rapid reemployment. With active labor market expenditures and short-term, rather than long-term unemployment insurance, Scandinavians had shorter average unemployment spells but high wage replacement rates. Today Denmark, the Netherlands, and other welfare states pursue 'flexicurity' policies to allow firms to dismiss unneeded workers who are nonetheless protected from poverty during jobless transitions and are helped to find new jobs. Similarly, in Germany, flexible measures to prevent unemployment, such as 'mini-jobs' and shortened hours ('Kurzeit'), keep workers from being laid off entirely during downturns. In addition, wage subsidies may compensate employers for retaining their workers or hiring new ones.

Over time, European activation programs began to exhibit some common trends. Training and active labor market programs contracted. Work requirements were enforced with sanctions, and paid work was emphasized over subsidized, sheltered employment, or community service. Greater financial incentives were offered to make work pay. Benefit recipients received more tailored, individualized attention from case managers, but also had to sign personal action plans or integration contracts specifying a long-term course of action toward integration. Meanwhile, the administration of activation was outsourced to private employment services that made greater use of Internet-based job searches and on-line job banks. Job search supports, personalized employment services, and enforcement of job searches vary cross-nationally. Yet the impact of activation on poverty appears limited. One study of 26 European countries found that, controlling for social assistance benefit levels, there was no clear additional effect of public services or ALMP on material deprivation.

Ironically, even though many governments have reduced long-term or on-the-job training that could enhance labor productivity, the European Union has adopted the idea of 'social investment' and 'flex-security' policies. This 'inclusionary' approach aims to reduce long-term joblessness by encouraging mobility and reemploying people in high wage jobs. Yet pressuring the jobless to accept any job offer by threatening to reduce benefits for refusals leaves vulnerable many extremely poor people who are not ready for work – the hungry, homeless, ill, addicted, and materially deprived children. Tacitly acknowledging two tiers of unemployment, the EU instituted a Fund for European Aid to the Most Deprived. It aims to help 4 million people with nonfinancial material assistance (food, clothing, shoes, soap, etc.) and will be financed from the Cohesion Policy budget, rather the European Social Fund, the main instrument of the 'social investment' approach to fight poverty. Thus, an un/deserving distinction among the poor is arising in Europe too.

Growth, Employment, and Poverty

Alongside explicit antipoverty programs, most countries rely on macroeconomic growth and labor market policies to reduce poverty indirectly through insuring gainful employment for all. Over time, industrial societies expected antipoverty policies to contribute to economic growth, not impede it, as investments in human capital – health, education, and training – enhanced productivity. To enable workers to share in rising affluence, governments statutorily increased the returns to work through minimum wages or mandated employer benefits, or encourage organized labor and business to bargain collectively over these. In recent years, Brazil, China, and other emerging economies have raised the minimum wage as an

antipoverty measure. US evidence shows that increases in the minimum wage to 'livable' levels substantially raise earnings at the bottom of the distribution, reduce wage inequality, and do not impede job creation, although there are probably spillover effects on those earning slightly above the minimum wage (Belman and Wolfson, 2014).

Many consider economic growth to be both a necessary and sufficient condition for reducing extreme poverty. In line with longstanding active labor market programs, the EU has tied poverty reduction and social inclusion to employment and growth. Europe 2020 is the EU's post-Lisbon social investment strategy for smart, sustainable, and inclusive growth. This politically attractive approach to poverty reduction aims to lift at least 20 million people out of poverty and social exclusion and to increase employment of the population to 75%. To reach these targets, the strategy includes a flagship initiative, the Platform against Poverty and Social Exclusion. The Platform calls for coordination of labor market policies, minimum income support, health care, education, housing, and access to basic banking across EU countries; earmarked European Social Funds (through PROGRESS) for fighting poverty and social exclusion; evidence-based social policy evaluations; and partnerships with civil society and participation of people experiencing poverty.

The modernization of social protection in EU states is intended to promote social investment throughout the life course. This means guaranteeing youth a job or training, promoting prime age employment, integrating social assistance and unemployment insurance, and making pensions sustainable. Workforce development, dual apprenticeship, on-the-job training, and adult and continuing education programs aim to increase human capital and thereby, wages. Internships, transitional jobs, and other forms of temporary or trial employment are opportunities for jobless workers to convince employers to hire them permanently. To the extent that people can more easily find jobs that match their skills, then employment services, job search programs, and mobility assistance will also contribute to reducing poverty.

Yet, given reduced spending on training, some scholars are concerned that relatively expensive social investment programs may 'crowd out' traditional welfare programs. Indeed, the EU poverty rate has remained around 15% since the mid-1990s, despite rising employment rates. This was partly because jobs went to new labor market entrants, not the long-term unemployed. But it was also because employment in the new economy no longer insures an escape from poverty. Hours of work are as important as minimum wage rates and earned income tax credits in determining poverty.

Europe's social investment approach to poverty reduction apparently entails trade-offs, or a 'trilemma' making it hard simultaneously to ensure that: (1) the unemployed are not poor, (2) budgetary constraints are recognized, and (3) employment growth is sufficient to reduce benefit dependency. Until the Great Recession, the trilemma was avoided by making it more difficult to claim and stay on benefits. Even without reducing the level or replacement rates of benefits, social spending was kept under control, wage inequalities remained largely unchanged, and employment rose significantly. European governments balanced the books mainly by lowering social protection for those outside the labor market. Externalizing costs kept outsiders' poverty rates high (Cantillon, 2011). The economic crisis added to social exclusion, material deprivation, and poverty, requiring special measures for the 'most deprived.'

Conditional Cash Transfers

Conditional cash transfers (CCT) impose obligations on poor recipients besides work. Varying across countries in generosity, cash assistance is made conditional upon certain eligibility criteria and actions such as enrolling children in public schools, getting vaccinations or regular doctor's check-ups, and other investments in human capital. CCTs address the intergenerational transmission of poverty and foster social inclusion and development.

CCTs expanded rapidly after 2001. The World Bank says over 30 developing countries now have CCT programs and the number is growing. Some of the best known are Brazil's Bolsa Escola program started in the 1990s and its Bolsa Familia that provides monthly cash payments to poor households if their children are enrolled in school. Mexico's Oportunidades, originally called Progresa, is the principal antipoverty program of the Mexican government. It helps poor families in rural and urban communities improve the education, health, and nutrition of their children. Supplemented by Apoyo Alimentario, Oportunidades reaches about a fourth of those in need and has reduced hunger despite rising food prices. Chile's Solidario, Colombia's Familias en Acción, Peru's Juntos, and other CCTs throughout Latin America and the Caribbean all pair cash transfers with human capital investments. More recently, CCTs are being developed in the Middle East and Asia as well.

CCTs have resulted in sizable reductions in poverty among recipients – especially when the transfer has been sufficient, well targeted, and structured in a way that does not discourage recipients from taking other actions to escape poverty. The spread of cash transfers alongside other kinds of social safety net programs helped an estimated 50 million people in 2010 raise their incomes above $1.25 a day (Ravillion, 2013). Because CCTs provide a steady income, they have helped protect poor households from the worst effects of unemployment, catastrophic illness, and other sudden income shocks. Since virtually all CCTs make cash transfers to women, they may have increased female bargaining power too.

The transfers do have weaknesses. Although intended to be universal, people with disabilities or in remote areas with insufficient public services or transportation may be excluded from such programs. Poor education and health systems limit the benefits of CCT programs. There is also some evidence that, once recipients enter the labor force, CCTs do little to increase the quality of education, learning, nor salaries.

Poverty Policies in the Global South

Less developed countries have more poverty than the OECD countries, and fewer means to reduce it. Besides CCTs, the Global South frequently relies on in-kind safety nets, mostly subsidized food and fuel. In the 1990s, international agencies often helped developing countries subsidize basic commodities,

but international loans created large, unsustainable debts. Increasing prices of staple goods could set off social unrest as well. Therefore, international agencies and developing states now approach poverty reduction through the pursuit of economic growth and development. Whereas Western welfare states provide essential public services and redistribute income in response to democratic demands, Eastern states are sometimes called 'productivist' or 'developmental' because they integrate social programs with top-down macroeconomic growth policies.

To the extent that poverty reduction programs have been introduced in the Global South, they are mainly found in middle-income countries. Different regions have education, health, and social insurance programs with different levels of coverage and different public and private mixes. In most countries, both democratic and nondemocratic, public employees are usually offered good social protection. Newly democratic middle-income countries in East Asia and Eastern Europe are establishing or expanding unemployment insurance, although it is limited in Latin America. Some East Asian countries have instituted universalist, redistributive social policies with high coverage, while authoritarian Malaysia and Singapore took a more liberal approach to safety nets. Latin America had 'informal security regimes' that until recently relied upon traditional family and community relationships to meet basic needs. More recently, neoliberal reforms have expanded CCTs as well as the privatization of old-age insurance, to produce a 'liberal-informal' welfare regime. Yet some Latin American countries also offer widely available, but means-tested health and education programs. After the fall of communism, Eastern Europe used early retirement disability and family allowances to cope with unemployment, but the programs did not help people escape poverty. They are turning to unemployment insurance.

China and some other command economies do provide income support and subsidized commodities, but tie them to a fixed place of residence and workplace. Since the 1980s, China has also dedicated resources to the development of poor areas in expectation of geographic spillovers. This territorial approach has both impeded labor mobility and left illegal urban migrants exposed to poverty, even though poverty in China has fallen with economic growth.

Another, more indirect approach to poverty reduction in low-income countries is micro-credit or micro-finance programs. Making it easier for poor people to borrow makes it possible to invest and improve their incomes and provide insurance to smooth consumption during downturns. Reflecting the large size of informal economies where small enterprises and self-employment prevail, access to credit – often through mutual savings funds or rotating credit associations – can move people, women especially, over the poverty threshold. While often rooted in ethnic or local bonds of enforceable trust, these micro-credit programs are nevertheless vulnerable to external risks and rarely enable micro-enterprises to grow much in size. However, social entrepreneurship is an increasingly popular neoliberal approach to development among international organizations.

Many countries lack domestic safety net or antipoverty programs entirely. Without stabilizers of domestic demand, global recessions can propel large numbers of people into poverty and create political unrest. Lower-income countries lack the resources and administrative capacity to establish full-fledged social assistance programs. At best, a few like Kenya and Zambia have launched pilot programs. Some therefore refer to African welfare regimes as 'insecurity' or 'ill-fare' regimes. The World Bank's Social Funds aim to help the poorest countries institute targeted antipoverty programs and finance public works in poor communities. Provided corruption does not divert funds, such development projects can contribute to human development and provide a rapid local economic stimulus. Since the 1990 *World Development Report,* a 'world free of poverty' became the World Bank's overarching goal.

Abstract

Sociologists and other social scientists have used a variety of approaches in explaining and describing poverty, as well as methods to define and measure poverty. Herein, we examine several approaches and concepts of poverty measurement. Each approach has its strengths and weaknesses, but all end up with some definition or description of poverty and the attributes of the poor. Also debated are the sociological theories of why poverty exists, and its relation to family, culture, and context. Sociologists have provided important tools for testing causal hypotheses concerning the explanations, causes, and cures for poverty regardless of how it is measured. These include place, culture, stratification, space, race, gender, imprisonment, and other popular theories of poverty in sociology. Sociological studies of poverty have both a rich heritage and have become an important area of research in increasingly unequal rich and poor societies.

The author thanks David Chancellor for expert research and manuscript preparation assistance. Any views expressed in this article are those of the author alone and not those of the Institute for Research on Poverty.

Sociologists have long written about the topic of poverty, as have economists and other social scientists. The fundamental concept of poverty concerns itself with having too few resources or capabilities to participate fully in a society. As Blank (2008) reminds us, "poverty is an inherently vague concept and developing a poverty measure involves a number of relatively arbitrary assumptions." Ultimately, all social scientists need to first establish the breadth and depth of this social phenomenon called 'poverty' before they can meaningfully analyze it and explore its ultimate causes and remedies. We begin here with sociological approaches to the origins and nature of poverty, both measurement and theory. Then we move on to concepts and techniques used to measure poverty by sociologists and other social scientists in both national and cross-national contexts. In all circumstances, we focus on sociologists' contributions to understanding the nature, causes, and consequences of poverty.

Sociologists, Poverty Theory, and Poverty Measurement – Some History

Sociologists have traditionally been more interested in the explanation of poverty than in its measurement, though almost all sociologists believe that poverty statistics are meaningful social indicators of basic needs (Piachaud, 1987; Townsend, 1979; Ringen, 1985; Brady, 2003a). In general, sociologists are critical of the economist's perspective of choice models whereby individuals control their own destiny and are therefore often the cause of their own poverty (Piachaud, 1987). Some such as Gans (1972) even feel that poverty has a functional role to play in capitalist society. In any case, social scientists need to first establish the breadth and depth of poverty in order to analyze it and explore its ultimate causes and remedies. The 'whats' of poverty measurement are fairly well accepted by all social scientists and are covered below. But the reasons why we have poverty, why it persists in some places and not in others, and its consequences are more controversial and here sociologists have played a prominent role.

For instance, consider 'social stratification,' a categorization of people into rankings of socioeconomic tiers based on factors like wealth, income, social status, occupation, and power. Different theories of sociology lead to different explanations for poverty. Structural-functionalists maintain that stratification and inequality are inevitable and beneficial to society at large, or at least to the well-off in society (Davis and Moore, 1945; Rank, 2011). The role of social stratification in poverty has been studied by Massey (2008) and popularized by others such as Beeghley (2007) and Eitzen and Eitzen Smith (2008). Conflict theorists argue that stratification is dysfunctional and harmful to society, and that it results in competition between the rich and the poor as individuals act for their own economic advantage (Kerbo, 2012). Some believe that poverty and inequality are created and maintained by people trying to regulate or control other individuals (Piven and Cloward, 1993).

Such differences of opinion also spread over into sociological interest centered around the ideas of the 'culture' of poverty and the effects of 'place' on poverty – which are often measured differently and are therefore hard to compare. The urban/central city/ghetto aspects of this issue are discussed in the work of Rainwater (1970), Wilson (1987), Anderson (1999), Massey and Denton (1993), and Massey (1996). Harrington's classic work, *The Other America*, covers rural deprivation as well (Harrington, 1962, 1981). Roles of culture, power, social structure, and other factors largely out of control of the individual are the main forces which sociologists use to explain poverty. The basic working hypothesis is that individuals are strongly influenced by the physical and cultural context in which they live. 'Neighborhood' exerts a strong influence on behavior and concentrated poverty in central city ghettos and therefore has a strong negative effect on future life chances and long-run deprivation.

Sociologists and demographers also have importantly pioneered the effects of family structure on poverty, especially its effects on children and social mobility. Most prominent here is

the work of McLanahan (1985, 2004, 2009), McLanahan and Sandefur (1994), and McLanahan and Percheski (2008). Eggebeen and Lichter (1991) and Brown (2004) have also made important contributions here. Some of this work spills over into the realm of parenting and social class per se (Kohn, 1963; Lareau, 2002), as well as the environment of child poverty (Evans, 2004). Closely related is social mobility out of poverty where works by Vaisey (2010), Vermeulen (2000), and Young (2006) have become standard references as far as mobility up from poverty is related to culture and race. In contrast, the structural limits to cultural perspectives are also emphasized by Brady (2003b) and Rank et al. (2003).

In one particularly important area of stratification, that is related to criminal justice, sociologists are the leaders in research on the effects of incarceration on poverty and disconnection from work, public income support, and effects on the family. Most recently, a spate of articles and books on poor younger men and issues related to poverty and incarceration, jobs, social safety nets, and minority men have appeared as we begin to finally address the serious negative effects of prison on neighborhoods, families, and life after prison. Perhaps the most appropriately titled contribution is "Collateral Costs" (Western and Pettit, 2010). But then see also Goffman (2014), Smeeding et al. (2011), Harding et al. (2014), Morenoff and Harding (forthcoming), Wyse et al. (2014), Harding (2010), Wakefield and Wildeman (2013), Western and Wildeman (2009), Wildeman (2009), Western (2006, 2010), Pettit (2012), Pager (2007), and Manza and Uggen (2006), all of whom are among the most prominent researchers in this arena.

Resources other than access to material goods might be important determinants of poverty. The literature on the 'time poor' has grown in recent years after a nascent period. The argument is that time is often the scarcest commodity in market work-oriented societies. Further, time spent on home production is often undervalued or not valued at all. The gender bias in time use is therefore at the heart of these types of analyses (Vickery, 1977). In particular, research has focused on the time crunch on single parents who must both earn a living in the labor market and care for their children (England and Folbre, 1999; Folbre, 1994; Shipler, 2005).

Concepts of Poverty and Techniques of Poverty Measurement

The rest of our discussion is framed by **Figure 1**, which reviews most of the possibilities of poverty concepts and measures. The conceptual underpinnings of poverty measures come from sociology (Grusky and Kanbur, 2006), economics (Lampman, 1964), social statistics (Orshansky, 1965), and social policy (Rowntree, 1901; Booth, 1903). All of the social sciences use or refer to objective and quantitative poverty measurement, usually but not always using a single dimension of 'resources,' income, and several notions of 'needs' standards: those that are relative, absolute, and, closely related, anchored poverty lines (e.g., see Iceland, 2005). We often choose income poverty because of its domination in modern (post-1960s) poverty studies and because of its linkages to the income inequality literature that follows. But wealth poverty is also commonly addressed by sociologists (Shapiro, 2004), as well as family budget models, related to making ends meet as pioneered by Stack (1978) and, more recently, by Edin and Lien (1997) and Halpern-Meekin et al. (2015).

Income or 'living-standards' poverty measurement began in the Anglo-Saxon countries and dates back at least to Rowntree (1901), who was the first to employ the concept of a poverty line in his empirical work on York, England. And thanks to his enterprise, and that of Booth (1903), who invented the idea of a poverty line for London, we have a meaningful social indicator of basic needs (see for instance, Townsend, 1979, 1993; Piachaud, 1987; Ringen, 1985; Ravallion, 2014). We also note that official poverty measurement began as an Anglo-American social indicator. But since then, 'official' measures of poverty (or measures of 'low income') now exist in over 100 countries and for Europe as a whole (Eurostat, 2005). The United States (DeNavas-Walt et al., 2012; Short, 2013) and the United Kingdom (Department for Work and Pensions, 2012) have

Figure 1 Concepts and measures of poverty. Source: Adapted from Dhongde, S., 20 March 2013. Measuring Multidimensional Poverty in the U.S. Presentation at Institute for Research on Poverty, University of Wisconsin–Madison, Madison, WI; Smeeding, T.M., 2014. Poverty measurement. In: Brady, D., Burton, L. (Eds.), The Oxford Handbook of Poverty and Society. Oxford University Press.

long standing 'official' poverty series. Statistics Canada publishes the number of households with incomes below a 'low-income cutoff' on an irregular basis, as does the Australian government with those below the 'Henderson line.' In Northern Europe and Scandinavia, the debate centers instead on the level of income at which minimum benefits for social programs should be set. In other words, their concept of insufficient 'low income' is directly fed into programmatic responses to social needs (Björklund and Freeman, 1997; Marx and Nelson, 2013; Ravallion, 2014). In addition to these 'objective' poverty measures, several have used 'subjective' measures of poverty and well-being, including income sufficiency (Ravallion, 2014; Van Praag, 1968; Groedhart et al., 1977; Hagenaars and van Praag, 1985; Clark and D'Ambrosio, 2014).

Figure 1 suggests that objective studies of poverty can be classified as quantitative, qualitative (ethnographic), or both. And in the latter two areas, sociologists have made the major contributions to the field. The classic ethnographic studies of poor neighborhoods (both urban and rural), jobs, street corners, and the culture of poverty were pioneered by Harrington (1981), Leibow (1967), Lewis (1969), Wilson (2010), Patterson (2001), and Bourgois (2001). More recently, new, younger sociologists have taken the field to new levels, including Harding et al. (2010), Goffman (2014), often looking specifically at race, ethnicity, and immigration issues, as in Linn and Harris (2008). And ethnographies of low-wage work such as those by Shipler (2005) and Ehrenreich (2001) show how fragile is the edge between poverty and utter destitution for the working poor.

Perhaps, the most powerful approaches to poverty measurement are situations where both qualitative and quantitative works are combined. This type of 'mixed methods' research is done by sociologists in both rich countries (Edin and Lien, 1997; Halpern-Meekin et al., 2015; Tach and Halpern-Meekin, 2014) and poor countries (Carvalho and White, 1997). This research brings both the richness of qualitative descriptions of life in poverty and a large enough sample of budgets or quantitative measures to add some structure and depth to the ethnographies and personal vignettes that support the numbers.

Most measures of quantitative poverty are single dimensional. But concern about the concept of multidimensional poverty is also flourishing in sociology and economics. Official measures of material deprivation, and material hardship exist mainly in Europe, where the European term for a similarly disaffected population is a measure of "social exclusion" (Room, 1999; Hills, 1999; Glennerster et al., 1999). Europe adopted the official Laeken set of social indicators to measure social exclusion in 1995, including the at-risk-of-poverty indicator, with an explicit objective of reducing poverty and social exclusion (Marlier et al., 2007). Indeed, indicators of material deprivation now form part of the Europe 2020 target of poverty reduction (Atkinson and Marlier, 2010: Chapter 6). The study of material hardship in the United States has attracted some attention by sociologists (e.g., see Heflin et al., 2011; Mayer and Jencks, 1989). And it is also related to the so-called 'underclass' which goes beyond poverty alone to include all persons with dysfunctional behaviors living in 'bad' neighborhoods (Mincy et al., 1990; Jencks and Peterson, 1990).

Because there is no single commonly accepted way to measure poverty among social scientists, there is a desire to go beyond the popularly used income poverty definition as a single dimension measure (**Figure 1**), and so there exists a wide variety of additional poverty measures which substitute for or complement the preponderance of income-based measures used by quantitative sociologists and economists (e.g., see Haveman, 2009; Ruggles, 1990; Boltvinik, 2000).

In principle, if poverty is a multidimensional concept, it should reflect several aspects of personal well-being, not a single one, should it be income, consumption, or wealth, as shown in **Figure 1**. Forms of deprivation other than these can certainly be relevant to poverty measurement and to anti-poverty policymaking. A number of authors have suggested that separate measures of needs ought to be developed for different goods and services such as health care or education (Aaron, 1985). Housing and health care are most often mentioned in this context, though the latter is particularly of interest in medically unequal nations such as the United States, while the former is of much greater interest in the United Kingdom (UK, 1993).

Approaches to Poverty Measurement

While poverty measurement is an exercise that is particularly popular in the English-speaking countries, most rich nations share the Anglo-Saxon concern over distributional outcomes and the well-being of the low-income population. There is no international consensus on guidelines for measuring poverty (Townsend, 1993), but international bodies such as the United Nations Children's Fund (UNICEF, 2000), the United Nations Development Programme (UNDP, 1999), the Organization for Economic Cooperation and Development (OECD, 2008, 2013), and the European Statistical Office (Eurostat, 1998, 2005), have published several cross-national studies of the incidence of poverty in rich countries. A large majority of these studies by sociologists as well as economists have been based on the Luxembourg Income Study (LIS) database which can be accessed at www.lisdatacenter.org. Some examples of these studies include Brady (2003a, 2003b, 2005), Brady et al. (2010), Förster (1993), Jäntti and Danziger (2000), Smeeding et al. (2000), Kenworthy (1999), Smeeding et al. (1990), and Smeeding (2006). More recently, the European Union (2005) and the OECD have regularized measurement of poverty by using different standards and data sources. Today one can also find harmonized measures from the World Bank that use both secondary (published) data- and micro data-based measures of consumption and income to determine those living below some particular amount of income per person per day, from $1.25 to $2.00 (Ravallion and Chen, 2011; Chen and Ravallion, 2012).

Most broadly, the quantitative single dimension measurement of poverty in rich, poor, and middle-income nations involves the comparison of some index of household well-being, like income, with household needs. When command over economic resources falls short of needs a household (or person or family) is classified as poor. Here well-being is economic, referring to the material resources available to a household. The concern with these resources among most

social scientists is generally not with material consumption alone, but also with the capabilities such resources give to household members so they can participate fully in society (Sen, 1983, 1992; Brandolini et al., 2010). These capabilities are inputs to social activities, and participation in social activities in return gives rise to a particular level of well-being as argued by sociologists like Rainwater (1990) and Coleman and Rainwater (1978). Methods for measuring a person's or household's capabilities differ according to the context in which one assesses them, either over time or across nations or among subpopulations within a nation, e.g., rural versus urban India.

As most sociologists agree, all advanced societies are highly stratified and, hence, some individuals have more resources than others. The opportunities for social participation are affected by the resources that a household disposes. These resources, the "family income package" (Rainwater et al., 1986; Rainwater and Smeeding, 2003), come from personal effort (earnings), family efforts, and others outside the household, principally governments but also other third parties like nonprofits. Money income is therefore a crucial resource. Of course, there are other important kinds of resources considered by sociologists, such as social capital, wealth, noncash benefits, primary education, and access to basic health care, all of which add to human capabilities (Coleman, 1988). These resources may be available more or less equally to all people in some societies, regardless of their money incomes. But there are also many forces in rich societies which reduce well-being by limiting capabilities for full participation in society, including inadequacies in neighborhoods where people live, racial and ethnic discrimination, neighborhood violence, low-quality public schools and other social services, lack of good jobs, and job instability. These factors increase economic insecurity, reduce human capabilities, and increase poverty, as dozens of analysts, including those mentioned above, have established.

Both consumption poverty and asset poverty have been proposed as an alternative to income poverty in rich nations (Meyer and Sullivan, 2012a, 2012b; Brandolini et al., 2010). And in a few nations, asset and income poverty can be combined into a joint measure (Gornick et al., 2009) as can consumption and income poverty (Meyer and Sullivan, 2012a, 2012b). But consumption and asset poverty measures are not yet ready for widespread use on a cross-national basis, despite their usefulness for some types of poverty measurement (e.g., many income-poor elderly consume more than their incomes due to dissaving and spending from assets).

Absolute, Relative, and Anchored Poverty in Rich and Selected Middle-Income Countries

Having settled on an index of resources, like income, one also needs a measure of need, or a poverty line to complete the objective, quantitative poverty measure in **Figure 1**. Economists and sociologists are often at odds on whether poverty is to be an absolute or relative measure. An absolute poverty standard is defined in terms of a level of purchasing power that is sufficient to buy a fixed bundle of basic necessities at a specific point in time. A relative standard, on the other hand, is defined relative to the typical income or consumption level in the wider society. The purchasing power of a relative poverty standard will change over time as society-wide income or consumption levels change, while an absolute poverty standard will change only with the prices of commodities it can buy. Most cross-national comparisons use the relative definition of poverty, especially since purchasing power parities to convert any absolute measure to country currency are subject to fluctuation and sometimes severe measurement error (Jäntti and Danziger, 2000), and most sociologists believe poverty ought to be measured relative to the time, place, and the standard of living where people live (Rainwater and Smeeding, 2003; Brady, 2003a).

And, in the broadest sense, all measures of poverty or economic needs are relative, because context is important to the definition of even 'absolute' needs. The World Bank uses poverty measures of $1.25 to $2 per person per day – or $1095 to $2190 per year for a family of three – for the developing nations of Africa, Central Asia, or Latin America (Chen and Ravallion, 2012). The measure makes no sense for a rich country today, but it might have served as poverty line for the United States set in the early 1900s. In contrast, the 2011 US 'absolute' poverty threshold was about $18 000 for a family of three – 8 to 17 times the World Bank's poverty line (depending on family size). And absolute and relative may also differ depending on the lower part of the income distribution in the country of interest. For instance, one-half of median income, the preferred relative poverty standard in the United States, is another 25–30% above the official US poverty line or 10–21 times the absolute poverty standard in poor countries. Moreover, as economic inequality has increased in most rich societies over the past 20 years, the study of relative deprivation and poverty has taken on a new life (Gottschalk and Smeeding, 2000; Gornick and Jäntti, 2013; OECD, 2011, 2013).

Cross-national comparisons of poverty in rich countries therefore rely heavily on openly and directly relative concepts of poverty, which are a reflection of the fact that a poverty standard or a minimum income standard ought to reflect the overall standard of living in society. One early source of this formalization (Abel-Smith and Townsend, 1965) came about in arguing that the officially defined minimum level of income in the United Kingdom, as represented by the National Assistance scale, should increase with the rising standard of living, and not just with consumer prices. It was Townsend's work in the early 1960s culminating in his famous 1979 book that really launched the relative poverty approach on a much wider scale.

As Townsend (1979: 31) wrote

> Individuals, families and groups in the population can be said to be in poverty when they lack the resources to obtain the type of diet, participate in the activities and have the living conditions and the amenities which are customary, or at least widely encouraged or approved in the societies to which they belong.

The measurement of relative poverty has more recently been generally operationalized with a definition of the poverty

line as a fraction of median income. Cross-national studies typically compare the percentage of persons living with income below some fraction of the family-size-adjusted national median income.

Measurement of relative poverty in the United States also began in the 1960s and was pioneered by Fuchs (1967), who followed the thinking of Townsend and Abel Smith and linked relative and absolute income poverty measurement. When Fuchs began his study, the absolute poverty measure in the United States begun by Lampman (1964) and then Orshansky (1965) was based on a poverty line of about $3000 for four persons. Fuchs pointed out that this was half of median income at that time and that one could think differently about relative poverty compared to absolute poverty (Gilbert, 2008: 136).

A relative poverty measure comparison is also consistent with a well-established theoretical perspective on poverty (Sen, 1983, 1992; and again, Townsend, 1979). However, the fraction of income at which the poverty line ought to be set is open to debate. Most cross-national studies (LIS, OECD) focus on half of the median income, following Fuchs and others. But many feel that a 50% of median standard is too low. It implies a poverty cutoff well below half the mean in unequal societies, and it also affects the country rankings. The European Statistical Office Working Group on Poverty Measurement has employed 60% of the national median income as the common poverty threshold for European Community poverty studies in the new millennium (Eurostat, 2005).

It is worthwhile to understand both absolute *and* relative poverty measures because they tell different things about absolute living standards as well as relative deprivation. Increasingly, the idea of 'anchored' poverty measures have become important and can be employed to indicate both relative and absolute poverty trends within a given nation. Anchored poverty measures begin with the same relative measure in 1 year (t) and then compare relative poverty in some future year (say year $t + 10$) to poverty measures against a poverty line that has been changed only for prices between year t and year $t + 10$. These measures are especially useful in periods of rapid expansion *or* contraction in an economy, where relative poverty may not change by a lot, but where absolute poverty does change due to economic growth or contraction (see Atkinson et al., 2002; Smeeding, 2006; Johnson and Smeeding, 2012; OECD, 2013). Any absolute poverty line is also therefore an anchored poverty line. The difference is that an anchored poverty line can be updated to any period which is policy relevant, given the analysis.

Summary

Sociologists and other social scientists have used a variety of approaches in explaining and describing poverty, as well as methods to define and measure poverty. Each approach has its strengths and weaknesses. More debated are the sociological theories of why poverty exists, and its relation to family, culture, and context.

Concepts and measures of poverty abound. Most quantitative poverty measures use income as a measure of resources, compared to some needs standard or poverty line. Both absolute and relative poverty line measurements tell us something about changes in living standards for low-income people. In order to measure both relative and absolute progress in countries, analysts increasingly use the idea of anchored poverty, whereby one fixes a poverty line within a country at the relative value in a given year and prices that forward to the most recent year. When one uses these concepts across a range of rich nations, one can trace out both changes in real or absolute living standards for low-income people, as well as relative progress or regress compared to the middle person in society.

Sociologists have also provided important tools for testing causal hypotheses concerning the explanations, causes, and cures for poverty regardless of how it is measured. These include place, culture, stratification, space, race, gender, imprisonment, and other popular theories of poverty in sociology. They are complemented by social indicator-based measures of inadequacy of time for market work, home work, and the nurturing and care of family members. Sociological studies of poverty have both a rich heritage and have become an important area of research in increasingly unequal rich and poor societies.

Power

Andrew S McFarland, University of Illinois at Chicago, Chicago, IL, USA

Abstract

Political power-as-causation is discussed: A causes B to change course against B's initial resistance. Models of power in policy-making such as pluralism, multiple elitism, and neopluralism; domination through socialization and social structure; Foucault's theory of power; and power in international systems and regimes are considered. Power-as-causation is contrasted to power-as-resources.

Leading political theorists, such as Machiavelli and Hobbes, have devoted much attention to 'political power.' As Robert A. Dahl noted (1957), power has a certain universality, whether it is called "power, influence, control, pouvoir, puissance, Macht, Herrschaft, Gewalt, imperium, potestas, auctoritas, potential, etc." This article first focuses on the concept of power defined as a type of social causation.

Power as Causation

During 1953–75, several leading political scientists developed the view of power as social causation, converging with an earlier, similar definition by Max Weber (Gerthe and Mills, 1946, 180). For power, after rejecting alternative definitions, Herbert Simon (1953: 503) cited a definition by Lasswell and Kaplan (1950): "The exercise of influence (influence process) consists in affecting policies of others than the self." In the formulation best known to political scientists, Dahl stated (1957: 202–203): "My intuitive idea of power, then, is something like this: A has power over B to the extent he can get B to do something that A would not otherwise do." James G. March stated (1955: 437): "… the set of all influence relations is here defined to be that subset of all causal relations such that the behavior of an individual appears as the terminal point in the causal linkage. Alternatively we can say that two individuals are in an influence relation if their behaviors are linked causally."

This leads to distinctions among different types of causal relations as they might relate to power. Political power refers to causal relations among humans, not to inanimate forces changing human behavior, as a hurricane might, for instance. Second, a distinction causing much confusion, one needs to distinguish situations in which the changed behavior reflects the intentions of the powerful actor. One might change the behavior of another in a way not intended, as when an incompetent lobbyist changes a legislator's vote to one different from one favored by the lobbyist. Some political scientists, such as March, are more comfortable with power causing changes in the direction intended by the powerful actor, and referring to the more general category of causing any changes as *influence*. On the other hand, the seminal articles by Simon and Dahl do not restrict power to intended changes in others' behavior.

Other examples of such causal relations would include power-as-suggestion: when A proposes a behavior change, B adopts the change without resistance. Another category of causal relations occurs when B resists, and A exercises rewards and sanctions, perhaps even force, to get B to change his/her behavior. This type of power may be called coercion.
